Foundations of Artificial Intelligence
20. Combinatorial Optimization: Introduction and Hill-Climbing

Malte Helmert

Universität Basel

April 8, 2016

20.1 Combinatorial Optimization

Introduction

previous chapters: classical state-space search
- find action sequence (path) from initial to goal state
- difficulty: large number of states ("state explosion")

next chapters: combinatorial optimization
⇝ similar scenario, but:
- no actions or transitions
- don't search for path, but for configuration ("state")
  with low cost/high quality

German: Zustandsraumexplosion, kombinatorische Optimierung, Konfiguration

Combinatorial Optimization: Overview

Chapter overview: combinatorial optimization

Combinatorial Optimization Problems

Definition (combinatorial optimization problem)

A combinatorial optimization problem (COP)
is given by a tuple $\langle C, S, opt, v \rangle$ consisting of:

- a set of (solution) candidates C
- a set of solutions $S \subseteq C$
- an objective sense $opt \in \{\min, \max\}$
- an objective function $v : S \to \mathbb{R}$

German: kombinatorisches Optimierungsproblem, Kandidaten,
Lösungen, Optimierungsrichtung, Zielfunktion

Remarks:

- "problem" here in another sense (= "instance")
  than commonly used in computer science
- practically interesting COPs usually have
  too many candidates to enumerate explicitly

Optimal Solutions

Definition (optimal)

Let $\mathcal{O} = \langle C, S, opt, v \rangle$ be a COP.

The optimal solution quality v^* of $\mathcal{O}$ is defined as

$$v^* = \begin{cases} \min_{c \in S} v(c) & \text{if } opt = \min \\ \max_{c \in S} v(c) & \text{if } opt = \max \end{cases}$$

(v^* is undefined if $S = \emptyset$.)

A solution s of $\mathcal{O}$ is called optimal if $v(s) = v^*$.

German: optimale Lösungsqualität, optimal

Combinatorial Optimization

The basic algorithmic problem we want to solve:

Combinatorial Optimization

Find a solution of good (ideally, optimal) quality
for a combinatorial optimization problem $\mathcal{O}$
or prove that no solution exists.

Good here means close to v^* (the closer, the better).

Relevance and Hardness

- There is a huge number of practically important combinatorial optimization problems.
- Solving these is a central focus of operations research.
- Many important combinatorial optimization problems are NP-complete.
- Most "classical" NP-complete problems can be formulated as combinatorial optimization problems.

⤳ Examples: TSP, VertexCover, Clique, BinPacking, Partition

German: Unternehmensforschung, NP-vollständig

Search vs. Optimization

Combinatorial optimization problems have

- a search aspect (among all candidates C, find a solution from the set S) and
- an optimization aspect (among all solutions in S, find one of high quality).

Pure Search/Optimization Problems

Important special cases arise when one of the two aspects is trivial:

- pure search problems:
  - all solutions are of equal quality
  - difficulty is in finding a solution at all
  - formally: v is a constant function (e.g., constant 0); opt can be chosen arbitrarily (does not matter)
- pure optimization problems:
  - all candidates are solutions
  - difficulty is in finding solutions of high quality
  - formally: $S = C$

20.2 Example

Example: 8 Queens Problem

8 Queens Problem

How can we

- place 8 queens on a chess board
- such that no two queens threaten each other?
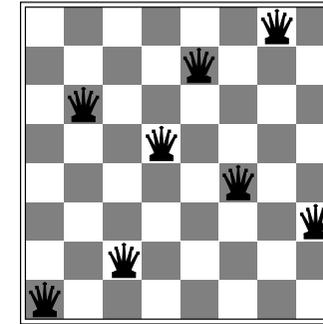

German: 8-Damen-Problem

- originally proposed in 1848
- variants: board size; other pieces; higher dimension

There are 92 solutions, or 12 solutions if we do not count
symmetric solutions (under rotation or reflection) as distinct.

Example: 8 Queens Problem

Problem: Place 8 queens on a chess board
such that no two queens threaten each other.

Is this candidate a solution?

Formally: 8 Queens Problem

How can we formalize the problem?

idea:

- obviously there must be exactly one queen in each file ("column")
- describe candidates as 8-tuples, where the i-th entry denotes the rank ("row") of the queen in the i-th file

formally: $\mathcal{O} = \langle C, S, opt, v \rangle$ with

- $C = \{1, \ldots, 8\}^8$
- $S = \{\langle r_1, \ldots, r_8 \rangle \mid \forall 1 \leq i < j \leq 8 : r_i \neq r_j \land |r_i - r_j| \neq |i - j|\}$
- v constant, opt irrelevant (pure search problem)

20.3 Local Search: Hill Climbing

Algorithms for Combinatorial Optimization Problems

How can we algorithmically solve COPs?

- formulation as classical state-space search
  ⤳ previous chapters
- formulation as constraint network ⤳ next week
- formulation as logical satisfiability problem ⤳ later
- formulation as mathematical optimization problem (LP/IP)
 ⤳ not in this course
- local search ⤳ this chapter and next chapter

Search Methods for Combinatorial Optimization

- main ideas of heuristic search applicable for COPs
  ⤳ states ≈ candidates
- main difference: no "actions" in problem definition
  - instead, we (as algorithm designers) can choose
    which candidates to consider neighbors
  - definition of neighborhood critical aspect
    of designing good algorithms for a given COP
- "path to goal" irrelevant to the user
  - no path costs, parents or generating actions
  ⤳ no search nodes needed

Local Search: Idea

main ideas of local search algorithms for COPs:

- heuristic h estimates quality of candidates
  - for pure optimization: often objective function v itself
  - for pure search: often distance estimate to closest solution
    (as in state-space search)
- do not remember paths, only candidates
- often only one current candidate ⤳ very memory-efficient
  (however, not complete or optimal)
- often initialization with random candidate
- iterative improvement by hill climbing
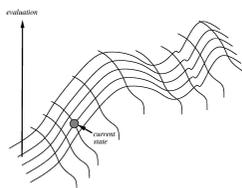

Hill Climbing

Hill Climbing (for Maximization Problems)

current := a random candidate
repeat:
    next := a neighbor of *current* with maximum h value
    if $h(next) \leq h(current)$:
   **return** *current*
    current := *next*

Remarks:

- search as walk "uphill" in a landscape
  defined by the neighborhood relation
- heuristic values define "height" of terrain
- analogous algorithm for minimization problems
  also traditionally called "hill climbing"
  even though the metaphor does not fully fit

Properties of Hill Climbing

- always terminates if candidate set is finite (Why?)
- no guarantee that result is a solution
- if result is a solution, it is locally optimal w.r.t. h, but no global quality guarantees

Example: 8 Queens Problem

Problem: Place 8 queens on a chess board
such that no two queens threaten each other.

possible heuristic: no. of pairs of queens threatening each other
(formalization as minimization problem)

possible neighborhood: move one queen within its file
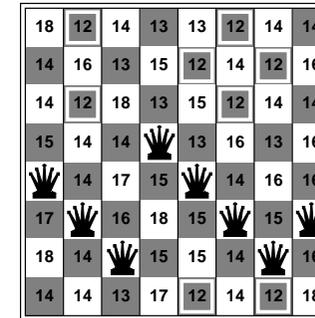

Performance of Hill Climbing for 8 Queens Problem

- problem has $8^8 \approx 17$ million candidates
  (reminder: 92 solutions among these)
- after random initialization, hill climbing finds a solution in around 14% of the cases
- only around 4 steps on average!

20.4 Summary

Summary

combinatorial optimization problems:

- ▶ find solution of good quality (objective value)
  among many candidates
- ▶ special cases:
  - ▶ pure search problems
  - ▶ pure optimization problems
- ▶ differences to state-space search:
  no actions, paths etc.; only "state" matters

often solved via local search:

- ▶ consider one candidate (or a few) at a time;
  try to improve it iteratively
