Automated Planning

> ### What is Automated Planning?
>
> "Planning is the art and practice of thinking before acting."
>
> — P. Haslum

⤳ finding plans (sequences of actions)
   that lead from an initial state to a goal state

our topic in this course: classical planning

- general approach to finding solutions
  for state-space search problems (Chapters 5–21)

- classical = static, deterministic, fully observable

- variants: probabilistic planning, planning under partial
  observability, online planning, . . .

Planning: Informally

given:

- state space description in terms of suitable problem description language (planning formalism)

required:

- a plan, i.e., a solution for the described state space (sequence of actions from initial state to goal)
- or a proof that no plan exists

distinguish between

- optimal planning: guarantee that returned plans are optimal, i.e., have minimal overall cost
- suboptimal planning (satisficing): suboptimal plans are allowed

What is New?

Many previously encountered problems are planning tasks:

- blocks world
- missionaries and cannibals
- 15-puzzle

New: we are now interested in general algorithms, i.e.,
the developer of the search algorithm does not know
the tasks that the algorithm needs to solve.

⤳ no problem-specific heuristics!

⤳ input language to model the planning task

About Section

Nothing New Here!

This section is a repetition of Section 5.2
of the chapter "State-Space Search: State Spaces".

Formalization of State Spaces

preliminary remarks:

- To properly handle search problems algorithmically, we need a formal definition.
- basic semantic concept: state spaces
- state spaces are (annotated) graphs
- paths to goal states correspond to solutions

State Spaces

Definition (state space)

A state space is a 6-tuple $\mathcal{S} = \langle S, A, cost, T, s_0, S_\star \rangle$ with

- S finite set of states
- A finite set of actions
- $cost : A \to \mathbb{R}_0^+$ action costs
- $T \subseteq S \times A \times S$ transition relation;
  deterministic in $\langle s, a \rangle$ (see next slide)
- $s_0 \in S$ initial state
- $S_\star \subseteq S$ set of goal states

- also: transition system
- German: Zustandsraum, Zustand, Aktion, Aktionskosten, Übergangsrelation (Transitionsrelation), Anfangszustand, Zielzustände

State Spaces: Transitions, Determinism

Definition (transition, deterministic)

Let $\mathcal{S} = \langle S, A, cost, T, s_0, S_\star \rangle$ be a state space.

The triples $\langle s, a, s' \rangle \in T$ are called transitions/state transitions.

We say "$\mathcal{S}$ has the transition $\langle s, a, s' \rangle$" if $\langle s, a, s' \rangle \in T$,
and we write $s \xrightarrow{a} s'$, or $s \rightarrow s'$ if not interested in a.

Transitions are deterministic in $\langle s, a \rangle$:
$s \xrightarrow{a} s_1$ and $s \xrightarrow{a} s_2$ with $s_1 \neq s_2$ is not allowed.

State Spaces: Terminology

terminology:

- predecessor, successor
- applicable action
- path, length, costs
- reachable
- solution, optimal solution

German: Vorgänger, Nachfolger, anwendbare Aktion, Pfad, Länge,
Kosten, erreichbar, Lösung, optimale Lösung

State Spaces with Declarative Representations

How do we represent state spaces in the computer?

previously: as black box

now: as declarative description

reminder: Chapter 6

State Spaces with Declarative Representations

represent state spaces declaratively:

- compact description of state space as input for algorithms
  ↝ state space exponentially larger than input
- algorithms work directly on compact description
↝ allows for automatic problem reformulation,
  simplification, abstraction, . . .

Compact Description of State Spaces

How to describe state spaces compactly?

Compact Description of Several States

- introduce state variables
- states: assignments to state variables
- ⤳ e.g., n binary state variables can describe 2^n states
- transitions and goal are compactly described
  with a logic-based formalism

different variants: different planning formalisms
