Board Games: Overview

chapter overview:

- ▶ 41. Introduction and State of the Art
- ▶ 42. Minimax Search and Evaluation Functions
- ▶ 43. Alpha-Beta Search
- ▶ 44. Monte-Carlo Tree Search: Introduction
- ▶ 45. Monte-Carlo Tree Search: Advanced Topics
- ▶ 46. AlphaGo and Outlook

42. Board Games: Minimax Search and Evaluation Functions

Minimax Search

Terminology for Two-Player Games

- ▶ Players are traditionally called MAX and MIN.
- Our objective is to compute moves for MAX (MIN is the opponent).
- ► MAX tries to maximize its utility (given by the utility function *u*) in the reached final position.
- ► MIN tries to minimize *u* (which in turn maximizes MINs utility).

16 5 / 17

Example: Tic-Tac-Toe

- ▶ game tree with player's turn (MAX/MIN) marked on the left
- ▶ last row: final positions with utility
- ▶ size of game tree?

42. Board Games: Minimax Search and Evaluation Functions

Minimax Search

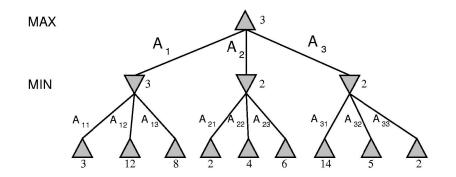

Minimax: Computation

- 1. depth-first search through game tree
- 2. Apply utility function in final position.
- 3. Compute utility value of inner nodes from below to above through the tree:
 - ► MIN's turn: utility is minimum of utility values of children
 - ▶ MAX's turn: utility is maximum of utility values of children
- 4. move selection for MAX in root: choose a move that maximizes the computed utility value (minimax decision)

Minimax Search

Minimax: Discussion

- ▶ Minimax is the simplest (decent) search algorithm for games
- ➤ Yields optimal strategy* (in the game theoretic sense, i.e., under the assumption that the opponent plays perfectly), but is too time consuming for complex games.
- ► We obtain at least the utility value computed for the root, no matter how the opponent plays.
- ► In case the opponent plays perfectly, we obtain exactly that value.

(*) for games where no cycles occur; otherwise things get more complicated (because the tree will have infinite size in this case).

rch 42. Board Games: Minimax Search and Evaluation Functions

Minimax: Pseudo-Code

```
function minimax(p)
```

```
if p is final position:

return \langle u(p), none \rangle

best_move := none

if player(p) = MAX:

v := -\infty
```

else:

```
v := \infty
for each \langle move, p' \rangle \in succ(p):
\langle v', best\_move' \rangle := minimax(p')
```

if (player(p) = MAX and v' > v) or (player(p) = MIN and v' < v): v := v'

best_move := move

return $\langle v, best_move \rangle$

Evaluation Functions

Evaluation Functions

- ▶ problem: game tree too big
- ▶ idea: search only up to certain depth
- depth reached: estimate the utility according to heuristic criteria (as if final position had been reached)

Example (evaluation function in chess)

- ▶ material: pawn 1, knight 3, bishop 3, rook 5, queen 9 positive sign for pieces of MAX, negative sign for MIN
- ▶ pawn structure, mobility, . . .

rule of thumb: advantage of 3 points → clear winning position

Accurate evaluation functions are crucial!

- ► High values should relate to high "winning chances" in order to make the overall approach work.
- At the same time, the evaluation should be efficiently computable in order to be able to search deeply.

42. Board Games: Minimax Search and Evaluation Functions

Evaluation Functions

Linear Evaluation Functions

Usually weighted linear functions are applied:

$$w_1 f_1 + w_2 f_2 + \cdots + w_n f_n$$

where w_i are weights, and f_i are features.

- assumes that feature contributions are mutually independent (usually wrong but acceptable assumption)
- ► allows for efficient incremental computation if most features are unaffected by most moves
- ▶ Weights can be learned automatically.
- ► Features are (usually) provided by human experts.

42. Board Games: Minimax Search and Evaluation Functions

Evaluation Functions

How Deep Shall We Search?

- ▶ objective: search as deeply as possible within a given time
- problem: search time difficult to predict
- solution: iterative deepening
 - sequence of searches of increasing depth
 - ▶ time expires: return result of previously finished search
- ► refinement: search depth not uniform, but deeper in "turbulent" positions (i.e., with strong fluctuations of the evaluation function) \(\sim \) quiescence search
 - example chess: deepen the search if exchange of pieces has started, but not yet finished

42. Board Games: Minimax Search and Evaluation Functions

Summa

42.3 Summary

15 / 17

Summary

- ▶ Minimax is a tree search algorithm that plays perfectly (in the game-theoretic sense), but its complexity is $O(b^d)$ (branching factor b, search depth d).
- ▶ In practice, the search depth must be limited → apply evaluation functions (usually linear combinations of features).
