May 3, 2017

M. Helmert, G. Röger (University of Basel) Foundations of Artificial Intelligence

Four Planning Formalisms

► A description language for state spaces (planning tasks) is called a planning formalism.

- ▶ We introduce four planning formalisms:
 - STRIPS (Stanford Research Institute Problem Solver)
 - 2 ADL (Action Description Language)
 - SAS⁺ (Simplified Action Structures)
 - 4 PDDL (Planning Domain Definition Language)
- ► STRIPS and SAS⁺ are the most simple formalisms; in the next chapters, we restrict our considerations to these.

34. Automated Planning: Planning Formalisms

34.2 STRIPS

Foundations of Artificial Intelligence

May 3, 2017

34. Automated Planning: Planning Formalisms

STRIPS: Basic Concepts

basic concepts of STRIPS:

- ▶ STRIPS is the most simple common planning formalism.
- state variables are binary (true or false)
- states s (based on a given set of state variables V) can be represented in two equivalent ways:
 - ightharpoonup as assignments $s:V \to \{F,T\}$
 - ightharpoonup as sets $s \subset V$.

where s encodes the set of state variables that are true in s

We will use the set representation.

- goals and preconditions of actions are given as sets of variables that must be true (values of other variables do not matter)
- effects of actions are given as sets of variables that are set to true and set to false, respectively

34. Automated Planning: Planning Formalisms

STRIPS Planning Task

Definition (STRIPS Planning Task)

A STRIPS planning task is a 4 tuple $\Pi = \langle V, I, G, A \rangle$ with

- V: finite set of state variables
- $ightharpoonup I \subset V$: the initial state
- $ightharpoonup G \subset V$: the set of goals
- A: finite set of actions, where for all actions $a \in A$, the following is defined:
 - ▶ $pre(a) \subseteq V$: the preconditions of a
 - ▶ $add(a) \subseteq V$: the add effects of a
 - ▶ $del(a) \subseteq V$: the delete effects of a
 - $ightharpoonup cost(a) \in \mathbb{N}_0$: the costs of a

German: STRIPS-Planungsaufgabe, Zustandsvariablen, Anfangszustand, Ziele, Aktionen, Add-/Delete-Effekte, Kosten remark: action costs are an extension of "traditional" STRIPS

M. Helmert, G. Röger (University of Basel) Foundations of Artificial Intelligence

State Space for STRIPS Planning Task

Definition (state space induced by STRIPS planning task)

Let $\Pi = \langle V, I, G, A \rangle$ be a STRIPS planning task.

Then Π induces the state space $S(\Pi) = \langle S, A, cost, T, s_0, S_{\star} \rangle$:

- ▶ set of states: $S = 2^V$ (= power set of V)
- \triangleright actions: actions A as defined in Π
- \triangleright action costs: cost as defined in \square
- ▶ transitions: $s \xrightarrow{a} s'$ for states s, s' and action a iff
 - ▶ $pre(a) \subseteq s$ (preconditions satisfied)
 - $s' = (s \setminus del(a)) \cup add(a)$ (effects are applied)
- ightharpoonup initial state: $s_0 = I$
- ▶ goal states: $s \in S_{\star}$ for state s iff $G \subseteq s$ (goals reached)

German: durch STRIPS-Planungsaufgabe induzierter Zustandsraum

34. Automated Planning: Planning Formalisms

Example: Blocks World in STRIPS

Example (A Blocks World Planning Task in STRIPS)

move actions encode moving a block from one block to another

example:

- $ightharpoonup pre(move_{A,B,C}) = \{on_{A,B}, clear_A, clear_C\}$
- ightharpoonup add(move_{A,B,C}) = {on_{A,C}, clear_B}
- $ightharpoonup del(move_{A,B,C}) = \{on_{A,B}, clear_C\}$
- $ightharpoonup cost(move_{A,B,C}) = 1$

34. Automated Planning: Planning Formalisms

Example: Blocks World in STRIPS

Example (A Blocks World Planning Task in STRIPS)

 $\Pi = \langle V, I, G, A \rangle$ with:

- $V = \{on_{AB}, on_{AC}, on_{BA}, on_{BC}, on_{CA}, on_{CB}, on_{C$ on-table_A, on-table_B, on-table_C, $clear_A$, $clear_B$, $clear_C$
- $I = \{on_{CA}, on-table_A, on-table_B, clear_C, clear_B\}$
- $ightharpoonup G = \{on_{A,B}, on_{B,C}\}$
- \blacktriangleright $A = \{move_{A,B,C}, move_{A,C,B}, move_{B,A,C}, \}$ $move_{B,C,A}$, $move_{C,A,B}$, $move_{C,B,A}$, to-table_{A,B}, to-table_{A,C}, to-table_{B,A}, to-table_{B,C}, to-table_{C,A}, to-table_{C,B}, from-table_{A.B}, from-table_{A.C}, from-table_{B,A}, from-table_{B,C}, from-table_{C,A}, from-table_{C,B}

34. Automated Planning: Planning Formalisms

Example: Blocks World in STRIPS

Example (A Blocks World Planning Task in STRIPS)

to-table actions encode moving a block from a block to the table.

example:

- $ightharpoonup pre(to-table_{AB}) = \{on_{AB}, clear_A\}$
- ightharpoonup add(to-table_{A,B}) = {on-table_A, clear_B}
- $ightharpoonup del(to-table_{A,B}) = \{on_{A,B}\}$
- $ightharpoonup cost(to-table_{A,B}) = 1$

May 3, 2017

34. Automated Planning: Planning Formalisms

Example: Blocks World in STRIPS

Example (A Blocks World Planning Task in STRIPS)

from-table actions encode moving a block from the table to a block

example:

- $ightharpoonup pre(from-table_{A,B}) = \{on-table_{A,clear_{A},clear_{B}}\}$
- ightharpoonup add(from-table_{A,B}) = $\{on_{A,B}\}$
- $ightharpoonup del(from-table_{A,B}) = \{on-table_{A}, clear_{B}\}$
- $ightharpoonup cost(from-table_{A,B}) = 1$

34. Automated Planning: Planning Formalisms

ADL, SAS+ and PDDL

34.3 ADL, SAS⁺ and PDDL

Why STRIPS?

- ► STRIPS is particularly simple.
- → simplifies the design and implementation of planning algorithms
- ▶ often cumbersome for the "user" to model tasks directly in STRIPS
- but: STRIPS is equally "powerful" to much more complex planning formalisms
- → automatic "compilers" exist that translate more complex formalisms (like ADL and SAS⁺) to STRIPS

Foundations of Artificial Intelligence

ADL, SAS+ and PDDL

Basic Concepts of ADL

34. Automated Planning: Planning Formalisms

basic concepts of ADL:

- ► Like STRIPS, ADL uses propositional variables (true/false) as state variables.
- preconditions of actions and goal are arbitrary logic formulas (action applicable/goal reached in states that satisfy the formula)
- ▶ in addition to STRIPS effects, there are conditional effects: variable v is only set to true/false if a given logical formula is true in the current state

M. Helmert, G. Röger (University of Basel) Foundations of Artificial Intelligence

M. Helmert, G. Röger (University of Basel) Foundations of Artificial Intelligence

ADL, SAS+ and PDDL

34. Automated Planning: Planning Formalisms

ADL, SAS+ and PDDL

Basic Concepts of SAS⁺

basic concepts of SAS+:

- very similar to STRIPS: state variables not necessarily binary, but with given finite domain (cf. CSPs)
- states are assignments to these variables (cf. CSPs)
- preconditions and goals given as partial assignments example: $\{v_1 \mapsto a, v_3 \mapsto b\}$ as preconditions (or goals)
 - ▶ If $s(v_1) = a$ and $s(v_3) = b$, then the action is applicable in s (or goal is reached)
 - values of other variables do not matter
- effects are assignments to subset of variables example: effect $\{v_1 \mapsto b, v_2 \mapsto c\}$ means
 - In the successor state s', $s'(v_1) = b$ and $s'(v_2) = c$.
 - ► All other variables retain their values.

M. Helmert, G. Röger (University of Basel) Foundations of Artificial Intelligence

17 / 20

34.4 Summary

Basic Concept of PDDL

- ▶ PDDL is the standard language used in practice to describe planning tasks.
- descriptions in (restricted) predicate logic instead of propositional logic (→ even more compact)
- other features like numeric variables and derived variables (axioms) for defining "macros" (formulas that are automatically evaluated in every state and can, e.g., be used in preconditions)
- ▶ There exist defined PDDL fragments for STRIPS and ADL: many planners only support the STRIPS fragment.

example: blocks world in PDDL

M. Helmert, G. Röger (University of Basel)

Foundations of Artificial Intelligence

May 3, 2017

34. Automated Planning: Planning Formalisms

Summary

planning formalisms:

- ▶ STRIPS: particularly simple, easy to handle for algorithms
 - binary state variables
 - preconditions, add and delete effects, goals: sets of variables
- ADL: extension of STRIPS
 - ▶ logic formulas for complex preconditions and goals
 - conditional effects
- ► SAS+: extension of STRIPS
 - state variables with arbitrary finite domains
- ▶ PDDL: input language used in practice
 - based on predicate logic (more compact than propositional logic)
 - only partly supported by most algorithms (e.g., STRIPS or ADL fragment)
