Optimality of A* with Reopening

In this chapter, we prove that A* with reopening is optimal when using admissible heuristics.

For this purpose, we

- give some basic definitions
- prove two lemmas regarding the behaviour of A*
- use these to prove the main result

Reminder: A* with Reopening

reminder: A* with reopening

```
A* with Reopening
open := new MinHeap ordered by \langle f, h \rangle
if h(\text{init}()) < \infty:
     open.insert(make_root_node())
distances := new HashTable
while not open.is_empty():
     n := open.pop_min()
     if distances.lookup(n.state) = none or g(n) < distances[n.state]:
           distances[n.state] := g(n)
           if is_goal(n.state):
                return extract_path(n)
           for each \langle a, s' \rangle \in \text{succ}(n.\text{state}):
                if h(s') < \infty:
                      n' := \mathsf{make\_node}(n, a, s')
                      open.insert(n')
return unsolvable
```

18. State-Space Search: Properties of A*, Part I

Solvable States

Definition (solvable)

A state s of a state space is called solvable if $h^*(s) < \infty$.

German: lösbar

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

Optimal Paths to States

Definition (g^*)

Let s be a state of a state space with initial state s_0 . We write $g^*(s)$ for the cost of the optimal (cheapest) path from s_0 to s (∞ if s is unreachable).

Remarks:

- \triangleright g is defined for nodes, g^* for states (Why?)
- ▶ $g^*(n.state) \le g(n)$ for all nodes ngenerated by a search algorithm (Why?)

Optimal Continuation Lemma

18.2 Optimal Continuation Lemma

18. State-Space Search: Properties of A*, Part I

Settled States in A*

Definition (settled)

A state s is called settled at a given point during the execution of A* (with or without reopening) if s is included in distances and distances[s] = $g^*(s)$.

German: erledigt

M. Helmert (University of Basel)

18. State-Space Search: Properties of A*, Part I

Optimal Continuation Lemma

Optimal Continuation Lemma

We now show the first important result for A* with reopening:

Lemma (optimal continuation lemma)

Consider A* with reopening using a safe heuristic at the beginning of any iteration of the while loop.

lf

- state s is settled.
- > state s' is a solvable successor of s, and
- an optimal path from s_0 to s' of the form $\langle s_0, \ldots, s, s' \rangle$ exists,

then

- \triangleright s' is settled or
- open contains a node n' with n'.state = s' and $g(n') = g^*(s')$.

German: Optimale-Fortsetzungs-Lemma

Optimal Continuation Lemma: Intuition

(Proof follows on the next slides.)

Intuitively, the lemma states:

If no optimal path to a given state has been found yet, open must contain a "good" node that contributes to finding an optimal path to that state.

(This potentially requires multiple applications of the lemma along an optimal path to the state.)

18. State-Space Search: Properties of A*, Part I

Optimal Continuation Lemma: Proof (1)

Proof.

Consider states s and s' with the given properties at the start of some iteration ("iteration A") of A*.

Because s is settled, an earlier iteration ("iteration B") set $distances[s] := g^*(s)$.

Thus iteration B removed a node n with n.state = s and $g(n) = g^*(s)$ from open.

 A^* did not terminate in iteration B. (Otherwise iteration A would not exist.) Hence n was expanded in iteration B.

.

18. State-Space Search: Properties of A*, Part I

Optimal Continuation Lemma

Optimal Continuation Lemma: Proof (2)

Proof (continued).

This expansion considered the successor s' of s.

Because s' is solvable, we have $h^*(s') < \infty$.

Because h is safe, this implies $h(s') < \infty$.

Hence a successor node n' was generated for s'.

This node n' satisfies the consequence of the lemma. Hence the criteria of the lemma were satisfied for s and s' after iteration B.

To complete the proof, we show: if the consequence of the lemma is satisfied at the beginning of an iteration, it is also satisfied at the beginning of the next iteration.

18. State-Space Search: Properties of A*, Part I

Optimal Continuation Lemma

Optimal Continuation Lemma: Proof (3)

Proof (continued).

- ▶ If s' is settled at the beginning of an iteration, it remains settled until termination.
- If s' is not yet settled and *open* contains a node n' with n'.state = s' and $g(n') = g^*(s')$ at the beginning of an iteration, then either the node remains in *open* during the iteration, or n' is removed during the iteration and s' becomes settled.

18.3 f-Bound Lemma

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

March 27, 2019

We need a second lemma:

Lemma (f-bound lemma)

Consider A* with reopening and an admissible heuristic applied to a solvable state space with optimal solution cost c^* .

Then open contains a node n with $f(n) \le c^*$ at the beginning of each iteration of the while loop.

German: f-Schranken-Lemma

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

March 27, 2019

18. State-Space Search: Properties of A*, Part I

f-Bound Lemma

f-Bound Lemma: Proof (1)

Proof.

Consider the situation at the beginning of any iteration of the while loop.

Let $\langle s_0, \ldots, s_n \rangle$ be an optimal solution.

(Here we use that the state space is solvable.)

Let s_i be the first state in the sequence that is not settled.

(Not all states in the sequence can be settled: s_n is a goal state, and when a goal state is inserted into distances, A* terminates.)

18. State-Space Search: Properties of A*, Part I

f-Bound Lemma

f-Bound Lemma: Proof (2)

Proof (continued).

Case 1: i = 0

Because s_0 is not settled yet, we are at the first iteration of the while loop.

Because the state space is solvable and h is admissible, we have $h(s_0) < \infty$.

Hence *open* contains the root n_0 .

We obtain: $f(n_0) = g(n_0) + h(s_0) = 0 + h(s_0) \le h^*(s_0) = c^*$, where "<" uses the admissibility of h.

This concludes the proof for this case.

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

March 27, 2019

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

f-Bound Lemma

f-Bound Lemma: Proof (3)

Proof (continued).

Case 2: i > 0

Then s_{i-1} is settled and s_i is not settled.

Moreover, s_i is a solvable successor of s_{i-1} and $\langle s_0, \ldots, s_{i-1}, s_i \rangle$ is an optimal path from s_0 to s_i .

We can hence apply the optimal continuation lemma (with $s = s_{i-1}$ and $s' = s_i$) and obtain:

- (A) s_i is settled, or
- (B) open contains n' with n'.state $= s_i$ and $g(n') = g^*(s_i)$.

Because (A) is false, (B) must be true.

We conclude: open contains n' with

$$f(n') = g(n') + h(s_i) = g^*(s_i) + h(s_i) \le g^*(s_i) + h^*(s_i) = c^*$$
, where "\le " uses the admissibility of h.

18. State-Space Search: Properties of A*, Part I

Optimality of A* with Reopening

Optimality of A* with Reopening

We can now show the main result of this chapter:

Theorem (optimality of A* with reopening)

A* with reopening is optimal when using an admissible heuristic.

18. State-Space Search: Properties of A*, Part I

Optimality of A* with Reopening

Optimality of A* with Reopening: Proof

Proof.

By contradiction: assume that the theorem is wrong.

Hence there is a state space with optimal solution cost c^* where A* with reopening and an admissible heuristic returns a solution with cost $c > c^*$.

This means that in the last iteration, the algorithm removes a node n with $g(n) = c > c^*$ from open.

With h(n.state) = 0 (because h is admissible and hence goal-aware), this implies:

$$f(n) = g(n) + h(n.state) = g(n) + 0 = g(n) = c > c^*.$$

A* always removes a node n with minimal f value from open. With $f(n) > c^*$, we get a contradiction to the f-bound lemma, which completes the proof.

M. Helmert (University of Basel)

18.5 Summary

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

March 27, 2019 25 / 26

18. State-Space Search: Properties of A*, Part I

Summary

- ► A* with reopening using an admissible heuristic is optimal.
- ► The proof is based on the following lemmas that hold for solvable state spaces and admissible heuristics:
 - optimal continuation lemma: The open list always contains nodes that make progress towards an optimal solution.
 - **f**-bound lemma: The minimum f value in the open list at the beginning of each A^* iteration is a lower bound on the optimal solution cost.
