Foundations of Artificial Intelligence

Local Search: GSAT

Local Search for SAT

- ▶ Apart from systematic search, there are also successful local search methods for SAT.
- ▶ These are usually not complete and in particular cannot prove unsatisfiability for a formula.
- ► They are often still interesting because they can find models for hard problems.
- ▶ However, all in all, DPLL-based methods have been more successful in recent years.

32. Propositional Logic: Local Search and Outlook

Local Search: GSAT

GSAT (Greedy SAT): Pseudo-Code

auxiliary functions:

- \triangleright violated(\triangle , I): number of clauses in \triangle not satisfied by I
- ightharpoonup flip(I, v): assignment that results from Iwhen changing the valuation of proposition v

```
function GSAT(\Delta):
repeat max-tries times:
      I := a random assignment
       repeat max-flips times:
              if I \models \Delta:
                    return /
              V_{\mathsf{greedy}} := \mathsf{the} \; \mathsf{set} \; \mathsf{of} \; \mathsf{variables} \; v \; \mathsf{occurring} \; \mathsf{in} \; \Delta
                            for which violated(\Delta, flip(I, v)) is minimal
              randomly select v \in V_{greedy}
             I := flip(I, v)
return no solution found
```

32. Propositional Logic: Local Search and Outlook

Local Search: GSAT

Local Search for SAT: Ideas

local search methods directly applicable to SAT:

- states: (complete) assignments
- goal states: satisfying assignments
- ▶ search neighborhood: change assignment of one variable
- ▶ heuristic: depends on algorithm; e.g., #unsatisfied clauses

M. Helmert, T. Keller (University of Basel)

Local Search: GSAT

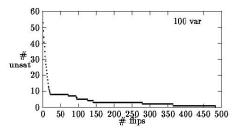

GSAT: Discussion

32. Propositional Logic: Local Search and Outlook

GSAT has the usual ingredients of local search methods:

- hill climbing
- randomness (although relatively little!)
- restarts

empirically, much time is spent on plateaus:

M. Helmert, T. Keller (University of Basel)

Foundations of Artificial Intelligence

Local Search: Walksat

32.2 Local Search: Walksat.

32. Propositional Logic: Local Search and Outlook

Local Search: Walksat

Walksat: Pseudo-Code

 $lost(\Delta, I, v)$: #clauses in Δ satisfied by I, but not by flip(I, v)

```
function Walksat(\Delta):
repeat max-tries times:
      I := a random assignment
      repeat max-flips times:
             if I \models \Delta:
                    return /
             C := \text{randomly chosen unsatisfied clause in } \Delta
             if there is a variable v in C with lost(\Delta, I, v) = 0:
                    V_{\text{choices}} := \text{all such variables in } C
             else with probability p<sub>noise</sub>:
                    V_{\mathsf{choices}} := \mathsf{all} \; \mathsf{variables} \; \mathsf{occurring} \; \mathsf{in} \; C
             else:
                    V_{\text{choices}} := \text{variables } v \text{ in } C \text{ that minimize lost}(\Delta, I, v)
             randomly select v \in V_{\text{choices}}
             I := flip(I, v)
return no solution found
```

32. Propositional Logic: Local Search and Outlook

Local Search: Walksat

Walksat vs. GSAT

Comparison GSAT vs. Walksat:

- much more randomness in Walksat because of random choice of considered clause
- "counter-intuitive" steps that temporarily increase the number of unsatisfied clauses are possible in Walksat
- → smaller risk of getting stuck in local minima

32. Propositional Logic: Local Search and Outlook

How Difficult Is SAT?

How Difficult Is SAT?

How Difficult is SAT in Practice?

- ► SAT is NP-complete.
- need exponential time in the worst case
- ► What about the average case?
- depends on how the average is computed (no "obvious" way to define the average)

M. Helmert, T. Keller (University of Basel)

Foundations of Artificial Intelligence

April 22, 2020

32. Propositional Logic: Local Search and Outlook

How Difficult Is SAT?

SAT: Polynomial Average Runtime

Good News (Goldberg 1979)

construct random CNF formulas with n variables and k clauses as follows:

In every clause, every variable occurs

- \triangleright positively with probability $\frac{1}{3}$,
- ightharpoonup negatively with probability $\frac{1}{3}$
- ightharpoonup not at all with probability $\frac{1}{3}$.

Then the runtime of DPLL in the average case is polynomial in n and k.

→ not a realistic model for practically relevant CNF formulas (because almost all of the random formulas are satisfiable)

32. Propositional Logic: Local Search and Outlook

How Difficult Is SAT?

Phase Transitions

How to find interesting random problems?

conjecture of Cheeseman et al.:

Cheeseman et al., IJCAI 1991

Every NP-complete problem has at least one size parameter such that the difficult instances are close to a critical value of this parameter.

This so-called phase transition separates two problem regions, e.g., an over-constrained and an under-constrained region.

→ confirmed for, e.g., graph coloring, Hamiltonian paths and SAT

32. Propositional Logic: Local Search and Outlook

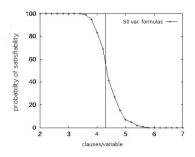

How Difficult Is SAT?

Phase Transitions for 3-SAT

Problem Model of Mitchell et al., AAAI 1992

- fixed clause size of 3
- in every clause, choose the variables randomly
- literals positive or negative with equal probability

critical parameter: #clauses divided by #variables phase transition at ratio ≈ 4.3

How Difficult Is SAT?

32. Propositional Logic: Local Search and Outlook

Phase Transition: Intuitive Explanation

with unit propagation.

by the search algorithm.

▶ If there are many clauses and hence the instance is

▶ If there are few clauses, there are many satisfying

► Close to the phase transition, there are many

assignments, and it is easy to find one of them.

"almost-solutions" that have to be considered

unsatisfiable with high probability, this can be shown efficiently

State of the Art

- - → http://www.satlive.org/
- ▶ conferences on SAT since 1996 (annually since 2000)
 - → http://www.satisfiability.org/
- competitions for SAT algorithms since 1992 → http://www.satcompetition.org/
 - ▶ largest instances have more than 1 000 000 literals
 - different tracks (e.g., SAT vs. SAT+UNSAT; industrial vs. random instances)

32. Propositional Logic: Local Search and Outlook

32.4 Outlook

32. Propositional Logic: Local Search and Outlook

More Advanced Topics

DPLL-based SAT algorithms:

- efficient implementation techniques
- accurate variable orders
- clause learning

local search algorithms:

- efficient implementation techniques
- adaptive search methods ("difficult" clauses are recognized after some time, and then prioritized)

SAT modulo theories:

extension with background theories (e.g., real numbers, data structures, . . .)

M. Helmert, T. Keller (University of Basel) Foundations of Artificial Intelligence

32. Propositional Logic: Local Search and Outlook

32.5 Summary

M. Helmert, T. Keller (University of Basel)

Foundations of Artificial Intelligence

April 22, 2020

22 / 24

32. Propositional Logic: Local Search and Outlook

Summary (1)

- ▶ local search for SAT searches in the space of interpretations; neighbors: assignments that differ only in one variable
- has typical properties of local search methods: evaluation functions, randomization, restarts
- example: GSAT (Greedy SAT)
 - ▶ hill climbing with heuristic function: #unsatisfied clauses
 - randomization through tie-breaking and restarts
- example: Walksat
 - ► focuses on randomly selected unsatisfied clauses
 - but does not follow the heuristic always, but also injects noise
 - consequence: more randomization as GSAT and lower risk of getting stuck in local minima

32. Propositional Logic: Local Search and Outlook

Summary (2)

- more detailed analysis of SAT shows: the problem is NP-complete, but not all instances are difficult
- randomly generated SAT instances are easy to satisfy if they contain few clauses, and easy to prove unsatisfiable if they contain many clauses
- ▶ in between: phase transition

M. Helmert, T. Keller (University of Basel) Foundations of Artificial Intelligence
