Minimax Search

Terminology for Two-Player Games

- ▶ Players are traditionally called MAX and MIN.
- Our objective is to compute moves for MAX (MIN is the opponent).
- ► MAX tries to maximize its utility (given by the utility function *u*) in the reached terminal position.
- ► MIN tries to minimize *u* (which in turn maximizes MINs utility).

41. Board Games: Minimax Search and Evaluation Functions

Minimay Search

Example: Tic-Tac-Toe

- ▶ game tree with player's turn (MAX/MIN) marked on the left
- ► last row: terminal positions with utility
- ▶ size of game tree?

41. Board Games: Minimax Search and Evaluation Functions

Minimax Search

Minimax: Computation

- depth-first search through game tree
- Apply utility function in terminal position.
- Compute utility value of inner nodes from below to above through the tree:
 - ► MIN's turn: utility is minimum of utility values of children
 - MAX's turn: utility is maximum of utility values of children
- move selection for MAX in root: choose a move that maximizes the computed utility value (minimax decision)

Minimax Search

Minimax: Discussion

- Minimax is the simplest (decent) search algorithm for games
- ➤ Yields optimal strategy* (in the game-theoretic sense, i.e., under the assumption that the opponent plays perfectly), but is too time-consuming for complex games.
- ► We obtain at least the utility value computed for the root, no matter how the opponent plays.
- ► In case the opponent plays perfectly, we obtain exactly that value.
- (*) for games where no cycles occur; otherwise things get more complicated (because the tree will have infinite size in this case).

41. Board Games: Minimax Search and Evaluation Functions

v := v'

return $\langle v, best_move \rangle$

best move := move

Evaluation Functions

41.2 Evaluation Functions

41. Board Games: Minimax Search and Evaluation Functions

Evaluation Functions

Evaluation Functions

- problem: game tree too big
- ▶ idea: search only up to certain depth
- depth reached: estimate the utility according to heuristic criteria (as if terminal position had been reached)

Example (evaluation function in chess)

- material: pawn 1, knight 3, bishop 3, rook 5, queen 9
 positive sign for pieces of MAX, negative sign for MIN
- pawn structure, mobility, . . .

rule of thumb: advantage of 3 points → clear winning position

Accurate evaluation functions are crucial!

- ▶ High values should relate to high "winning chances" in order to make the overall approach work.
- At the same time, the evaluation should be efficiently computable in order to be able to search deeply.

41. Board Games: Minimax Search and Evaluation Functions

Evaluation Functions

Linear Evaluation Functions

Usually weighted linear functions are applied:

$$w_1f_1 + w_2f_2 + \cdots + w_nf_n$$

where w_i are weights, and f_i are features.

- assumes that feature contributions are mutually independent (usually wrong but acceptable assumption)
- ► allows for efficient incremental computation if most features are unaffected by most moves
- ▶ Weights can be learned automatically.
- Features are (usually) provided by human experts.

The idea dates back at least to Lolli (1763).

Evaluation Functions

How Deep Shall We Search?

- **objective**: search as deeply as possible within a given time
- **problem:** search time difficult to predict
- solution: iterative deepening
 - sequence of searches of increasing depth
 - time expires: return result of previously finished search
- ► refinement: search depth not uniform, but deeper in "turbulent" positions (i.e., with strong fluctuations of the evaluation function) \(\sim \) quiescence search
 - example chess: deepen the search after capturing moves

Summar

41.3 Summary

41. Board Games: Minimax Search and Evaluation Functions

Summan

Summary

- Minimax is a tree search algorithm that plays perfectly (in the game-theoretic sense), but its complexity is $O(b^d)$ (branching factor b, search depth d).
