Automated Planning

What is Automated Planning?

"Planning is the art and practice of thinking before acting."

— P. Haslum

⤳ finding plans (sequences of actions)
that lead from an initial state to a goal state

our topic in this course: classical planning

- general approach to finding solutions
  for state-space search problems (Chapters 5–19)
- classical = static, deterministic, fully observable
- variants: probabilistic planning, planning under partial
  observability, online planning, . . .

Planning: Informally

given:

- state space description in terms of suitable problem description language (planning formalism)

required:

- a plan, i.e., a solution for the described state space (sequence of actions from initial state to goal)
- or a proof that no plan exists

distinguish between

- optimal planning: guarantee that returned plans are optimal, i.e., have minimal overall cost
- suboptimal planning (satisficing):
  suboptimal plans are allowed

What is New?

Many previously encountered problems are planning tasks:

- blocks world
- missionaries and cannibals
- 15-puzzle

New: we are now interested in general algorithms, i.e.,
the developer of the search algorithm does not know
the tasks that the algorithm needs to solve.

⤳ no problem-specific heuristics!

⤳ input language to model the planning task

- 35.–36. Planning Heuristics: Delete Relaxation
- 37. Planning Heuristics: Abstraction
- 38.–39. Planning Heuristics: Landmarks

Repetition: State Spaces

About This Section

Nothing New Here!

This section is a repetition of Section 5.2
of the chapter "State-Space Search: State Spaces".

Formalization of State Spaces

preliminary remarks:

- to cleanly study search problems we need a formal model
- fundamental concept: state spaces
- state spaces are (labeled, directed) graphs
- paths to goal states represent solutions
- shortest paths correspond to optimal solutions

State Spaces

Definition (state space)

A state space or transition system is a 6-tuple
$\mathcal{S} = \langle S, A, cost, T, s_0, S_\star \rangle$ with

- S: finite set of states
- A: finite set of actions
- $cost : A \to \mathbb{R}_0^+$ action costs
- $T \subseteq S \times A \times S$ transition relation; deterministic in $\langle s, a \rangle$ (see next slide)
- $s_0 \in S$ initial state
- $S_\star \subseteq S$ set of goal states

German: Zustandsraum, Transitionssystem, Zustände, Aktionen, Aktionskosten, Transitions-/Übergangsrelation, deterministisch, Anfangszustand, Zielzustände

State Spaces: Transitions, Determinism

Definition (transition, deterministic)

Let $\mathcal{S} = \langle S, A, cost, T, s_0, S_\star \rangle$ be a state space.

The triples $\langle s, a, s' \rangle \in T$ are called (state) transitions.

We say $\mathcal{S}$ has the transition $\langle s, a, s' \rangle$ if $\langle s, a, s' \rangle \in T$.
We write this as $s \xrightarrow{a} s'$, or $s \to s'$ when a does not matter.

Transitions are deterministic in $\langle s, a \rangle$: it is forbidden to have both $s \xrightarrow{a} s_1$ and $s \xrightarrow{a} s_2$ with $s_1 \neq s_2$.

State Spaces: Terminology

terminology:

- predecessor, successor
- applicable action
- path, length, costs
- reachable
- solution, optimal solution

German: Vorgänger, Nachfolger, anwendbare Aktion, Pfad, Länge, Kosten, erreichbar, Lösung, optimale Lösung

State Spaces with Declarative Representations

How do we represent state spaces in the computer?

previously: as black box

now: as declarative description

reminder: Chapter 6

State Spaces with Declarative Representations

represent state spaces declaratively:

- compact description of state space as input to algorithms
  ⤳ state spaces exponentially larger than the input
- algorithms directly operate on compact description
- ⤳ allows automatic reasoning about problem:
  reformulation, simplification, abstraction, etc.

Reminder: Blocks World
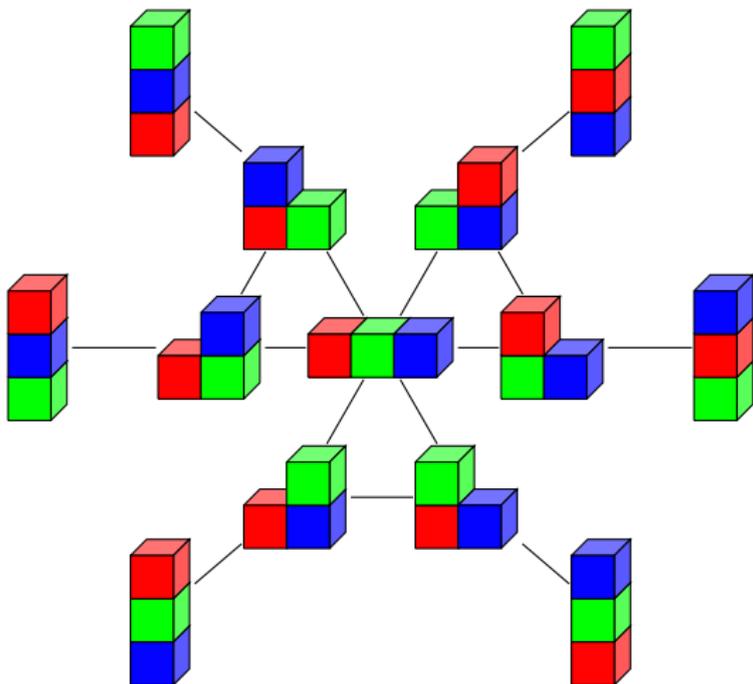

problem: *n* blocks ⤳ more than *n*! states

Compact Description of State Spaces

How to describe state spaces compactly?

Compact Description of Several States

- introduce state variables
- states: assignments to state variables
- ⤳ e.g., n binary state variables can describe 2^n states
- transitions and goal are compactly described
  with a logic-based formalism

different variants: different planning formalisms
