Board Games: Overview

chapter overview:

- ▶ 40. Introduction and State of the Art
- ▶ 41. Minimax Search and Evaluation Functions
- ▶ 42. Alpha-Beta Search
- ▶ 43. Stochastic Games
- ▶ 44. Monte-Carlo Tree Search Framework
- ▶ 45. Monte-Carlo Tree Search Configurations

Monte-Carlo Tree Search: Pseudo-Code

```
function visit_node(n)
if is_terminal(n.position):
     utility := utility(n.position)
else:
     s := n.get\_unvisited\_successor()
     if s is none:
           n' := apply\_tree\_policy(n)
           utility := visit\_node(n')
     else:
           utility := simulate\_game(s)
           n.add_and_initialize_child_node(s, utility)
n.N := n.N + 1
n.\hat{v} := n.\hat{v} + \frac{utility - n.\hat{v}}{n.N}
return utility
```

45. Board Games: Monte-Carlo Tree Search Configurations

Simulation Phase

idea: determine initial utility estimate by simulating game following a default policy

Definition (default policy)

Let $S = \langle S, A, T, s_I, S_{\star}, utility, player \rangle$ be a game.

A default policy for S is a mapping $\pi_{default}: S \times A \mapsto [0,1]$ s.t.

- **1** $\pi_{default}(s, a) > 0$ implies that there is $s' \in S$ with T(s, a, s') > 0 and

in the call to simulate_game(s'),

- \triangleright the default policy is applied starting from position s'(determining decisions for both players)
- ightharpoonup until a terminal position s^* is reached
- \triangleright and *utility*(s^*) is returned

Keller & F. Pommerening (University of B Foundations of Artificial Intelligence

45. Board Games: Monte-Carlo Tree Search Configurations

Implementations

"default" implementation: Monte-Carlo random walk

- in each position, select a move uniformly at random
- ▶ until a terminal position is reached
- very cheap to compute
- ▶ uninformed → usually not sufficient for good results
- ► not always cheap to simulate

alternative: game-specific default policy

- hand-crafted or
- ► learned offline

Sylvain Gelly and David Silver, Combining Online and Offline Knowledge in UCT (ICML, 2007)

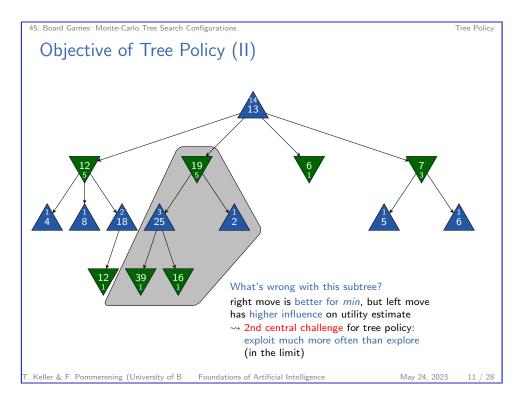

45. Board Games: Monte-Carlo Tree Search Configurations

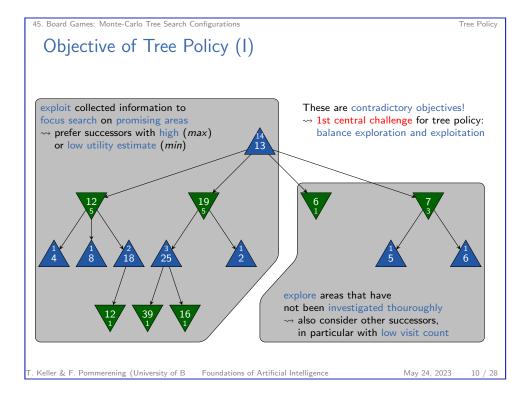

Default Policy vs. Evaluation Function

- ▶ default policy simulates a game to obtain utility estimate ~→ default policy must be evaluated in many positions
- ▶ if default policy is expensive to compute or poorly informed, simulations are expensive
- b observe: simulating a game to the end is just a specific implementation of an evaluation function
- modern implementations replace default policy with evaluation function that directly computes a utility estimate
- → MCTS is a heuristic search algorithm

45. Board Games: Monte-Carlo Tree Search Configurations

Asymptotic Optimality

Definition (asymptotic optimality)

Let S be a game with set of positions S and let $v^*(s)$ denote the (true) utility of position $s \in S$.

Let $n.\hat{v}^k$ denote the utility estimate of a search node n after k trials.

An MCTS algorithm is asymptotically optimal if

$$\lim_{k\to\infty} n.\hat{v}^k = v^*(n.\text{position})$$

for all search nodes n.

T. Keller & F. Pommerening (University of B Foundations of Artificial Intelligence

45. Board Games: Monte-Carlo Tree Search Configurations

Asymptotic Optimality

a tree policy is asymptotically optimal if

- ▶ it explores forever:
 - every position is eventually added to the game tree and visited infinitely often (requires that the game tree is finite)
 - → after a finite number of trials, all trials end in a terminal position and the default policy is no longer used
- ▶ and it is greedy in the limit:
 - ▶ the probability that an optimal move is selected converges to 1
 - → in the limit, backups based on trials where only an optimal policy is followed dominate suboptimal backups

45. Board Games: Monte-Carlo Tree Search Configurations

45.3 Tree Policy: Examples

Keller & F. Pommerening (University of B Foundations of Artificial Intelligence

45. Board Games: Monte-Carlo Tree Search Configurations

May 24, 2023

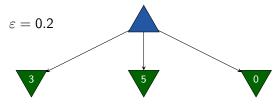

Tree Policy: Examples

45. Board Games: Monte-Carlo Tree Search Configurations

Tree Policy: Examples

ε -greedy: Idea and Example

- ightharpoonup tree policy with constant parameter ε
- with probability 1ε , pick a greedy move which leads to:
 - ► a successor with highest utility estimate (for max)
 - ► a successor with lowest utility estimate (for *min*)
- otherwise, pick a non-greedy successor uniformly at random

 $\mathbb{P}(n_1) = 0.1$

 $\mathbb{P}(n_2) = 0.8$

 $\mathbb{P}(n_3) = 0.1$

 $(\mathbb{P}(n))$ denotes probability that successor n is selected)

 ε -greedy: Optimality ε -greedy is not asymptotically optimal: converges to $\varepsilon = 0.2$ $0.8 \cdot 1 + 0.2 \cdot 10$ with $k \to \infty$ variants that are optimal in the limit exist (e.g., decaying ε , minimax backups)

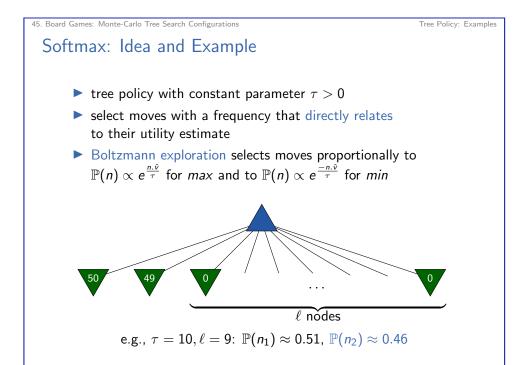

45. Board Games: Monte-Carlo Tree Search Configurations ε -greedy: Weakness problem: when ε -greedy explores, all non-greedy moves are treated equally $\underbrace{\varepsilon\text{-greedy}}_{\ell \text{ nodes}} = 0.2, \ell = 9 \colon \mathbb{P}(n_1) = 0.8, \, \mathbb{P}(n_2) = 0.02$

May 24, 2023

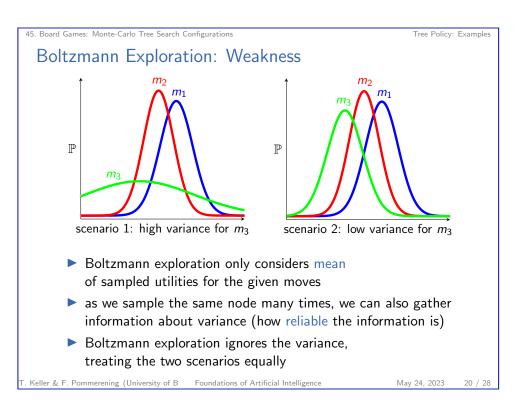

Keller & F. Pommerening (University of B Foundations of Artificial Intelligence

Boltzmann exploration: Optimality

Boltzmann exploration is not asymptotically optimal: $\tau = 10$ $0 \times 0.71 \cdot 1 + 0.29 \cdot 10$ 0

Keller & F. Pommerening (University of B Foundations of Artificial Intelligence

45. Board Games: Monte-Carlo Tree Search Configurations

Upper Confidence Bounds: Idea

balance exploration and exploitation by preferring moves that

- ► have been successful in earlier iterations (exploit)
- ► have been selected rarely (explore)

Keller & F. Pommerening (University of B Foundations of Artificial Intelligence

May 24, 2023

45. Board Games: Monte-Carlo Tree Search Configurations

Upper Confidence Bounds: Idea

upper confidence bound for max:

- ▶ select successor n' of n that maximizes $n'.\hat{v} + B(n')$
- ▶ based on utility estimate $n'.\hat{v}$
- \triangleright and a bonus term B(n')
- ▶ select B(n') such that $v^*(n')$.position $\leq n' \cdot \hat{v} + B(n')$ with high probability
- ightharpoonup idea: $n'.\hat{v} + B(n')$ is an upper confidence bound on $n'.\hat{v}$ under the collected information

(for min: maximize $-n'.\hat{v} + B(n')$)

Keller & F. Pommerening (University of B Foundations of Artificial Intelligence

45. Board Games: Monte-Carlo Tree Search Configurations

Tree Policy: Examples

Upper Confidence Bounds: UCB1

- use $B(n') = \sqrt{\frac{2 \cdot \ln n \cdot N}{n' \cdot N}}$ as bonus term
- bonus term is derived from Chernoff-Hoeffding bound, which
 - gives the probability that a sampled value (here: $n'.\hat{v}$)
 - \blacktriangleright is far from its true expected value (here: $v^*(n'.position)$)
 - \triangleright in dependence of the number of samples (here: n'.N)
- picks an optimal move exponentially more often in the limit

UCB1 is asymptotically optimal

45. Board Games: Monte-Carlo Tree Search Configurations

Comparison of Game Algorithms

May 24, 2023

45.4 Comparison of Game Algorithms

45. Board Games: Monte-Carlo Tree Search Configurations Comparison of Game Algorithms Minimax Tree full tree up to depth 4 What about alpha-beta search? → depth 5-6 (can be improved with good move ordering) Keller & F. Pommerening (University of B Foundations of Artificial Intelligence May 24, 2023 25 / 28

45. Board Games: Monte-Carlo Tree Search Configurations

45.5 Summary

45. Board Games: Monte-Carlo Tree Search Configurations Comparison of Game Algorithms MCTS Tree Keller & F. Pommerening (University of B Foundations of Artificial Intelligence May 24, 2023

45. Board Games: Monte-Carlo Tree Search Configurations

Summary

- tree policy is crucial for MCTS
 - \triangleright ϵ -greedy favors greedy moves and treats all others equally
 - ▶ Boltzmann exploration selects moves proportionally to an exponential function of their utility estimates
 - ▶ UCB1 favors moves that were successful in the past or have been explored rarely
- ▶ for each, there are applications where they perform best
- good default policies are domain-dependent and hand-crafted or learned offline
- using evaluation functions instead of a default policy often pays off
