November 22, 2017 — E4. Landmarks: Cut Landmarks & LM-cut Heuristic

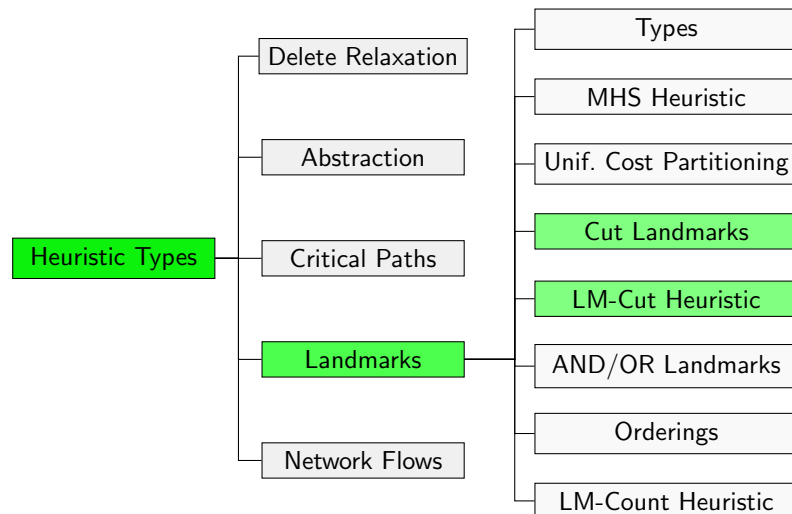

E4.1 Normal Form

E4.2 Cut Landmarks

E4.3 The LM-Cut Heuristic

E4.4 Summary

Content of this Course: Landmarks

Roadmap for this Chapter

- ▶ We first introduce a new **normal form for delete-free STRIPS tasks** that simplifies later definitions.
- ▶ We then present a method that **computes disjunctive action landmarks** for such tasks.
- ▶ We conclude with the **LM-cut heuristic** that builds on this method.

E4.1 Normal Form

Delete-Free STRIPS Planning Task in Normal Form (1)

In this chapter, we only consider **delete-free** STRIPS tasks in a new normal form:

Definition (Normal Form for Delete-free STRIPS)

A delete-free STRIPS planning task $\langle V, I, O, G \rangle$ (in set representation) is in **normal form** if

- ▶ I consists of exactly one element i : $I = \{i\}$
- ▶ G consists of exactly one element g : $G = \{g\}$
- ▶ Every action has at least one precondition.

Every delete-free STRIPS task can easily be transformed into an analogous task in normal form. (How?)

Delete-Free STRIPS Planning Task in Normal Form (2)

- ▶ In the following, we assume tasks in normal form.
- ▶ Providing O suffices to describe the overall task:
 - ▶ V are the variables mentioned in the operators in O .
 - ▶ always $I = \{i\}$ and $G = \{g\}$
- ▶ In the following, we only provide O for the description of the task.
- ▶ We write operator $o = \langle pre(o), add(o), \emptyset, cost(o) \rangle$ as $\langle pre(o) \rightarrow add(o) \rangle_{cost(o)}$, omitting braces for sets.

Example: Delete-Free Planning Task in Normal Form

Example

Operators:

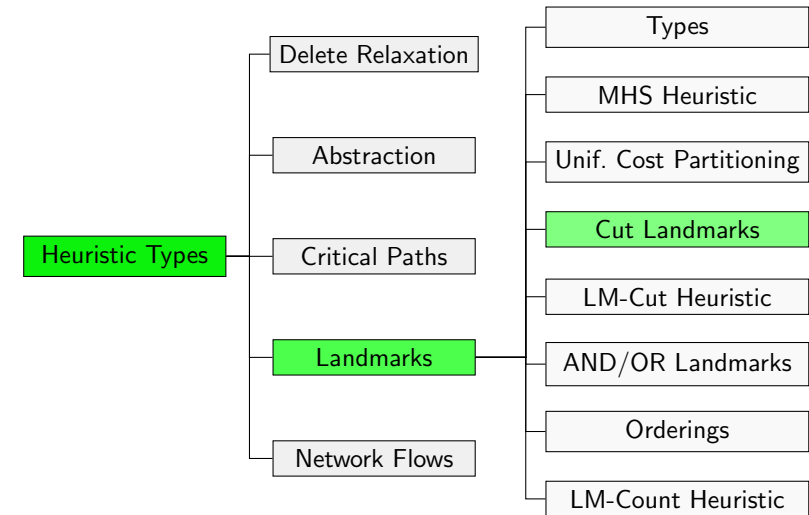

- ▶ $o_1 = \langle i \rightarrow x, y \rangle_3$
- ▶ $o_2 = \langle i \rightarrow x, z \rangle_4$
- ▶ $o_3 = \langle i \rightarrow y, z \rangle_5$
- ▶ $o_4 = \langle x, y, z \rightarrow g \rangle_0$

optimal solution to reach $\{g\}$ from $\{i\}$:

- ▶ **plan**: o_1, o_2, o_4
- ▶ **cost**: $3 + 4 + 0 = 7$ ($= h^+(\{i\})$ because plan is **optimal**)

E4.2 Cut Landmarks

Content of this Course: Landmarks

Justification Graphs

Definition (Precondition Choice Function)

A **precondition choice function (pcf)** $P : O \rightarrow V$ for a delete-free STRIPS task $\Pi = \langle V, \{i\}, O, \{g\} \rangle$ in normal form maps each operator to one of its preconditions (i.e. $P(o) \in \text{pre}(o)$ for all $o \in O$).

Definition (Justification Graphs)

Let P be a pcf for $\langle V, \{i\}, O, \{g\} \rangle$. The **justification graph** for P is the directed, edge-labeled graph $J = \langle V, E \rangle$, where

- ▶ the vertices are the variables from V , and
- ▶ E contains an edge $P(o) \xrightarrow{o} a$ for each $o \in O$, $a \in \text{add}(o)$.

Example: Justification Graph

Example

pcf P : $P(o_1) = P(o_2) = P(o_3) = i$, $P(o_4) = y$

$o_1 = \langle i \rightarrow x, y \rangle_3$
 $o_2 = \langle i \rightarrow x, z \rangle_4$
 $o_3 = \langle i \rightarrow y, z \rangle_5$
 $o_4 = \langle x, y, z \rightarrow g \rangle_0$

Cuts

Definition (Cut)

A **cut** in a justification graph is a subset C of its edges such that all paths from i to g contain an edge from C .

Cuts are Disjunctive Action Landmarks

Theorem (Cuts are Disjunctive Action Landmarks)

Let P be a pcf for $\langle V, \{i\}, O, \{g\} \rangle$ and C be a **cut** in the justification graph for P . The set of **edge labels** from C (formally $\{o \mid \langle v, o, v' \rangle \in C\}$) is a **disjunctive action landmark** for $I = \{i\}$.

Proof idea:

- ▶ The justification graph corresponds to a simpler problem where some preconditions (those not picked by the pcf) are ignored.
- ▶ Cuts are landmarks for this simplified problem.
- ▶ Hence they are also landmarks for the original problem.

Example: Cuts in Justification Graphs

Example

landmark $A = \{o_4\}$ (cost = 0)

- $o_1 = \langle i \rightarrow x, y \rangle_3$
- $o_2 = \langle i \rightarrow x, z \rangle_4$
- $o_3 = \langle i \rightarrow y, z \rangle_5$
- $o_4 = \langle x, y, z \rightarrow g \rangle_0$

Example: Cuts in Justification Graphs

Example

landmark $B = \{o_1, o_2\}$ (cost = 3)

- $o_1 = \langle i \rightarrow x, y \rangle_3$
- $o_2 = \langle i \rightarrow x, z \rangle_4$
- $o_3 = \langle i \rightarrow y, z \rangle_5$
- $o_4 = \langle x, y, z \rightarrow g \rangle_0$

Example: Cuts in Justification Graphs

Example

landmark $C = \{o_1, o_3\}$ (cost = 3)

- $o_1 = \langle i \rightarrow x, y \rangle 3$
- $o_2 = \langle i \rightarrow x, z \rangle 4$
- $o_3 = \langle i \rightarrow y, z \rangle 5$
- $o_4 = \langle x, y, z \rightarrow g \rangle 0$

Example: Cuts in Justification Graphs

Example

landmark $D = \{o_2, o_3\}$ (cost = 4)

- $o_1 = \langle i \rightarrow x, y \rangle 3$
- $o_2 = \langle i \rightarrow x, z \rangle 4$
- $o_3 = \langle i \rightarrow y, z \rangle 5$
- $o_4 = \langle x, y, z \rightarrow g \rangle 0$

Power of Cuts in Justification Graphs

- ▶ Which landmarks can be computed with the cut method?
- ▶ **all interesting ones!**

Proposition (perfect hitting set heuristics)

Let \mathcal{L} be the set of *all* “cut landmarks” of a given planning task with initial state I . Then $h^{MHS}(\mathcal{L}) = h^+(I)$.

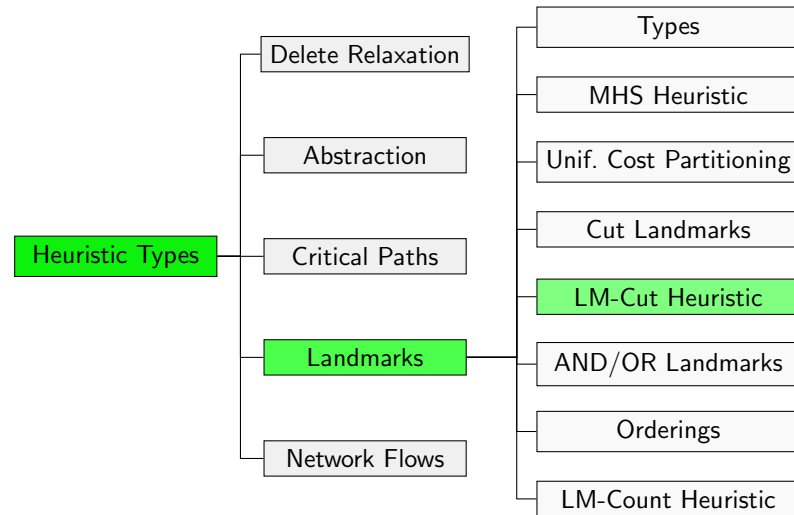

↔ Hitting set heuristic for \mathcal{L} is **perfect**.

Proof idea:

- ▶ Show 1:1 correspondence of hitting sets H for \mathcal{L} and plans, i.e., each hitting set for \mathcal{L} corresponds to a plan, and vice versa.

E4.3 The LM-Cut Heuristic

Content of this Course: Landmarks

LM-Cut Heuristic: Motivation

- ▶ In general, there are exponentially many pcfs, hence computing all relevant landmarks is not tractable.
 - ▶ The **LM-cut heuristic** is a method that chooses pcfs and computes cuts in a **goal-oriented** way.
 - ▶ As a side effect, it computes a (non-uniform) cost partitioning.
- ↪ currently the best admissible planning heuristic

LM-Cut Heuristic (1)

$h^{\text{LM-cut}}$: Helmert & Domshlak (2009)

Initialize $h^{\text{LM-cut}}(I) := 0$. Then iterate:

- ① Compute h^{max} values of the variables.
Stop if $h^{\text{max}}(g) = 0$.
- ② Let P be a pcf that chooses preconditions with maximal h^{max} value.
- ③ Compute the justification graph for P .
- ④ Compute a cut which guarantees $\text{cost}(L) > 0$ for the corresponding landmark L (next slide).
- ⑤ Increase $h^{\text{LM-cut}}(I)$ by $\text{cost}(L)$.
- ⑥ Decrease $\text{cost}(o)$ by $\text{cost}(L)$ for all $o \in L$.

LM-Cut Heuristic (2)

$h^{\text{LM-cut}}$: Helmert & Domshlak (2009)

- ④ Compute a cut which guarantees $\text{cost}(L) > 0$ for the corresponding landmark L as follows:
 - ▶ The **goal zone** V_g of the justification graph consists of all nodes that have a path to g where all edges are labelled with zero-cost operators.
 - ▶ The cut contains all edges $\langle v, o, v' \rangle$ such that $v \notin V_g$, $v' \in V_g$ and v can be reached from i without traversing a node in V_g .

Example: Computation of LM-Cut

Example

round 1: $P(o_4) = c \rightsquigarrow L = \{o_2, o_3\} [4]$

- $o_1 = \langle i \rightarrow a, b \rangle_3$
- $o_2 = \langle i \rightarrow a, c \rangle_4$
- $o_3 = \langle i \rightarrow b, c \rangle_5$
- $o_4 = \langle a, b, c \rightarrow g \rangle_0$

Example: Computation of LM-Cut

Example

round 1: $P(o_4) = c \rightsquigarrow L = \{o_2, o_3\} [4] \rightsquigarrow h^{\text{LM-cut}}(I) := 4$

- $o_1 = \langle i \rightarrow a, b \rangle_3$
- $o_2 = \langle i \rightarrow a, c \rangle_0$
- $o_3 = \langle i \rightarrow b, c \rangle_1$
- $o_4 = \langle a, b, c \rightarrow g \rangle_0$

Example: Computation of LM-Cut

Example

round 2: $P(o_4) = b \rightsquigarrow L = \{o_1, o_3\} [1]$

- $o_1 = \langle i \rightarrow a, b \rangle_3$
- $o_2 = \langle i \rightarrow a, c \rangle_0$
- $o_3 = \langle i \rightarrow b, c \rangle_1$
- $o_4 = \langle a, b, c \rightarrow g \rangle_0$

Example: Computation of LM-Cut

Example

round 2: $P(o_4) = b \rightsquigarrow L = \{o_1, o_3\} [1] \rightsquigarrow h^{\text{LM-cut}}(I) := 4 + 1 = 5$

- $o_1 = \langle i \rightarrow a, b \rangle_2$
- $o_2 = \langle i \rightarrow a, c \rangle_0$
- $o_3 = \langle i \rightarrow b, c \rangle_0$
- $o_4 = \langle a, b, c \rightarrow g \rangle_0$

Example: Computation of LM-Cut

Example

round 3: $h^{\max}(g) = 0 \rightsquigarrow$ done! $\rightsquigarrow h^{\text{LM-cut}}(I) = 5$

$o_1 = \langle i \rightarrow a, b \rangle_2$
 $o_2 = \langle i \rightarrow a, c \rangle_0$
 $o_3 = \langle i \rightarrow b, c \rangle_0$
 $o_4 = \langle a, b, c \rightarrow g \rangle_0$

Properties of LM-Cut Heuristic

Theorem

Let $\langle V, I, O, G \rangle$ be a delete-free STRIPS task in normal form.
 The **LM-cut heuristic is admissible**: $h^{\text{LM-cut}}(I) \leq h^*(I)$.

(Proof omitted.)

If Π is not delete-free, we can compute $h^{\text{LM-cut}}$ on Π^+ .
 Then $h^{\text{LM-cut}}$ is bound by h^+ .

E4.4 Summary

Summary

- ▶ **Cuts in justification graphs** are a general method to find disjunctive action landmarks.
- ▶ Hitting sets over **all cut landmarks** yield a **perfect heuristic** for delete-free planning tasks.
- ▶ The **LM-cut heuristic** is an admissible heuristic based on these ideas.
