G3.2 Symbolic Uniform-Cost Search

#### Introduction

- ▶ Previous chapter: Symbolic breadth-first search
- ▶ Optimal plans only guaranteed for unit-cost tasks (= all operators same cost)
- ▶ Optimal planning in explicit-state forward search:
  - (uninformed) uniform-cost search
  - ▶ (informed) A\* search

Analogous algorithms for symbolic (BDD-based) search?

M. Helmert, G. Röger (Universität Basel)

G3. Symbolic Search: Uniform-cost and A\* search

Symbolic Uniform-Cost Search

## Cost-separated Transition Relations

- Previously: one transition relation  $T_V(O)$  for all operators
- ▶ Now: several transition relations for operators of same cost
- ▶ Set  $\mathcal{T}$  of pairs (T, c), where T is a transition relation for one/some/all operators of cost c
  - ▶ All operators must be covered (and nothing else):

$$\bigcup_{(T,c)\in\mathcal{T}} r(T) = r(T_V(O))$$

► The cost must be correct:

For 
$$(T, c) \in \mathcal{T}$$
: if  $t \in r(T)$  then  $t \models \bigvee_{o \in O: cost(o) = c} \tau_V(o)$ 

Many possibilities to split up  $T_V(O)$  (discussed later)

Symbolic Uniform-Cost Search

December 18, 2017

#### Image Computation

▶ The apply function (previous chapter) computes the set of states S' that can be reached from a set of states S by applying one operator.

Planning and Optimization

- ▶ This is called the image of S wrt. transition relation  $T_V(O)$ .
- ▶ Now: image computation for arbitrary transition relations.

```
def image(B, T):
    B := bdd-intersection(B, T)
    for each v \in V:
         B := bdd-forget(B, v)
    for each v \in V:
         B := bdd-rename(B, v', v)
    return B
```

Exactly like apply but gets transition relation as argument.

M. Helmert, G. Röger (Universität Basel)

Planning and Optimization

## Symbolic Uniform-Cost Search (Positive Operator Costs)

```
\begin{aligned} & \textbf{def} \text{ symbolic-uniform-cost}(\textit{V}, \textit{I}, \textit{O}, \gamma) : \\ & \textit{goal} := \textit{build-BDD}(\gamma) \\ & \mathcal{T} := \textit{make-transition-relations}(\textit{V}, \textit{O}) \\ & \textit{open}_0 := \textit{bdd-state}(\textit{I}) \\ & \textbf{while} \ \exists \textit{g} : \textit{open}_{\textit{g}} \neq \textbf{0} : \\ & \textit{g} := \min\{\textit{g} \mid \textit{open}_{\textit{g}} \neq \textbf{0}\} \\ & \textit{closed}_{\textit{g}} := \textit{open}_{\textit{g}} \\ & \textbf{if} \ \textit{bdd-intersection}(\textit{open}_{\textit{g}}, \textit{goal}) \neq \textbf{0} : \\ & \textbf{return} \ \textit{construct-plan}(\textit{I}, \textit{O}, \textit{goal}, \textit{closed}_*, \textit{g}) \\ & \textbf{for all} \ (\textit{T}, \textit{c}) \in \mathcal{T} : \\ & \textit{open}_{\textit{g}+\textit{c}} := \textit{bdd-union}(\textit{open}_{\textit{g}+\textit{c}}, \\ & \textit{image}(\textit{open}_{\textit{g}}, \textit{T})) \\ & \textit{open}_{\textit{g}} := \textbf{0} \\ & \textbf{return} \ \textit{unsolvable} \end{aligned}
```

M. Helmert, G. Röger (Universität Basel)

Planning and Optimization

December 18, 2017

9 / 34

```
Pre-image Computation
```

- ▶ The image of *S* wrt. transition relation *T* computes the set of states that can be reached from *S* by applying a transition represented by *T*.
- ▶ The pre-image of S wrt. T is the set of states from which we can reach S by applying a transition represented by T.

M. Helmert, G. Röger (Universität Basel)

Symbolic Uniform-Cost Search

## Plan Extraction (Positive Operator Costs)

```
 \begin{aligned} \textbf{def} & \operatorname{construct-plan}(I,\ O,\ goal,\ closed_*,\ g) \colon \\ & \operatorname{cut} := \ bdd\text{-}intersection(goal,\ closed_g) \\ & \operatorname{init} := \ bdd\text{-}state(I) \\ & \pi := \langle \rangle \\ & \textbf{while} & \operatorname{bdd-intersection}(\operatorname{cut},\operatorname{init}) = \textbf{0} \colon \\ & \textbf{for} & o \in O \colon \\ & \operatorname{pre} := \operatorname{pre-image}(\operatorname{cut},\tau_V(o)) \\ & \textbf{if} & c := \ bdd\text{-}intersection(\operatorname{pre},\operatorname{closed}_{g-\operatorname{cost}(o)}) \neq \textbf{0} \colon \\ & \operatorname{cut} := c \\ & g := g - \operatorname{cost}(o) \\ & \pi := \langle o \rangle \pi \\ & \textbf{break} \end{aligned}
```

G3. Symbolic Search: Uniform-cost and A\* search

Symbolic Uniform-Cost Search

#### Zero-cost Operators

What is the problem with zero-cost operators?

- ► Search: could re-open *open<sub>g</sub>* after it was moved to *closed<sub>g</sub>*, possibly running into an infinite loop
  - → Apply all zero-cost operators before closing
- ▶ Plan extraction: could loop in zero-cost cycles
  - $\rightarrow$  special treatment

M. Helmert, G. Röger (Universität Basel)

Planning and Optimization

#### Breadth-first Exploration with Zero-cost Operators

```
\begin{aligned} & \textbf{def} \  \, \text{bfs-zero}(B,\,g,\,\mathcal{T},\,goal) \colon \\ & i := 0 \\ & \textit{closed}_{g,i} := B \\ & \textbf{while} \  \, B \neq \textbf{0} \  \, \text{and} \  \, \textit{bdd-intersection}(B,goal) = \textbf{0} \colon \\ & B' := \textbf{0} \\ & \textbf{for} \  \, (\mathcal{T},c) \in \mathcal{T}, c = 0 \colon \\ & B' := \textit{bdd-union}(B',\textit{image}(B,\mathcal{T})) \\ & B := \textit{bdd-intersection}(B',\textit{bdd-complement}(\textit{closed}_{g,i})) \\ & i := i+1 \\ & \textit{closed}_{g,i} := \textit{bdd-union}(B,\textit{closed}_{g,i-1}) \\ & \textbf{return} \  \, \textit{closed}_{g,i} \end{aligned}
```

Symbolic A\*

#### Heuristics

How can we generate symbolic heuristics?

- Symbolic Pattern Databases
  - ▶ Uniform-cost search can easily be adapted to regression search.
  - ► Can search backwards in abstract transition systems
  - ▶ BDD for closed states with (backwards-) g-value i is heuristic BDD for h = i.
- Merge-and-Shrink Abstractions
  - ► Algebraic Decision Diagrams are like BDDs but sink nodes are labeled with arbitrary numbers.
  - Can map states to numbers.
  - ► Cascading tables of merge-and-shrink heuristics with linear merge strategy can efficiently be transformed into an ADD.
  - ▶ Result can be used in symbolic search instead of BDD set.

G3. Symbolic Search: Uniform-cost and A\* search

Discussio

# Importance of Variable Ordering

- ▶ For good performance, we need a good variable ordering.
  - Variables that refer to the same state variable before and after operator application (v and v') should be neighbors in the transition relation BDD.
- ► This is important for the performance of *BDD-rename* in the *image* and *pre-image* computation.

G3. Symbolic Search: Uniform-cost and A\* search

Discussion

#### Transition Relations in $\mathcal{T}$

- We only required that all operators are represented by some  $(T, c) \in \mathcal{T}$  and that the costs are correct.
- Extreme cases:
  - One element  $(\tau_V(o), cost(o))$  for each operator o
  - ► Only one element for each operator cost, covering all operators of that cost.
- ► Trade-off:
  - ► Large number of entries leads to large number of image computations.
  - ► Size of *T* can grow exponentially with number of covered operators.
- ► There exist different aggregation strategies.

M. Helmert, G. Röger (Universität Basel) Pla

#### Performance

- ▶ In symbolic planning, blind search is often better than informed search.
- ▶ Practical implementations also perform regression or bidirectional search.
- ▶ This is only a minor modification of uniform-cost search.

M. Helmert, G. Röger (Universität Basel)

30 / 34

G3. Symbolic Search: Uniform-cost and A\* search

## Summary

- ► Symbolic search operates on sets of states instead of individual states as in explicit-state search.
- ▶ State sets and transition relations can be represented as BDDs.
- ▶ A good variable ordering and an efficient image computation are crucial for performance.
