Theory of Computer Science

# **D2.1 Polynomial Reductions**

# Polynomial Reductions: Idea

- Reductions are a common and powerful concept in computer science. We know them from Part C.
- The basic idea is that we solve a new problem by reducing it to a known problem.
- In complexity theory we want to use reductions that allow us to prove statements of the following kind: Problem A can be solved efficiently if problem B can be solved efficiently.
- For this, we need a reduction from A to B that can be computed efficiently itself (otherwise it would be useless for efficiently solving A).

# Polynomial Reductions

D2. Polynomial Reductions and NP-completeness

# Polynomial Reductions: Remarks

- Polynomial reductions are also called Karp reductions (after Richard Karp, who wrote a famous paper describing many such reductions in 1972).
- In practice, of course we do not have to specify a DTM for f: it just has to be clear that f can be computed in polynomial time by a deterministic algorithm.

# Polynomial Reductions: Example (1)

#### Definition (HAMILTONCYCLE)

HAMILTONCYCLE is the following decision problem:

- Given: undirected graph  $G = \langle V, E \rangle$
- Question: Does G contain a Hamilton cycle?

#### Reminder:

#### Definition (Hamilton Cycle)

A Hamilton cycle of G is a sequence of vertices in V,

- $\pi = \langle v_0, \ldots, v_n \rangle$ , with the following properties:
  - ▶  $\pi$  is a path: there is an edge from  $v_i$  to  $v_{i+1}$  for all  $0 \le i < n$

• 
$$\pi$$
 is a cycle:  $v_0 = v_n$ 

- $\pi$  is simple:  $v_i \neq v_j$  for all  $i \neq j$  with i, j < n
- $\pi$  is Hamiltonian: all nodes of V are included in  $\pi$

# Polynomial Reductions: Example (2)

#### Definition (TSP)

TSP (traveling salesperson problem) is the following decision problem:

- ▶ Given: finite set  $S \neq \emptyset$  of cities, symmetric cost function *cost* :  $S \times S \rightarrow \mathbb{N}_0$ , cost bound  $K \in \mathbb{N}_0$
- ▶ Question: Is there a tour with total cost at most K, i.e., a permutation  $\langle s_1, \ldots, s_n \rangle$  of the cities with  $\sum_{i=1}^{n-1} cost(s_i, s_{i+1}) + cost(s_n, s_1) \leq K$ ?

D2. Polynomial Reductions and NP-completeness

#### Polynomial Reductions: Example (3)

#### Theorem (HAMILTONCYCLE $\leq_p$ TSP) HAMILTONCYCLE $\leq_p$ TSP.

Proof.  $\rightsquigarrow$  blackboard

Gabriele Röger (University of Basel)

### Exercise: Polynomial Reduction

#### Definition (HAMILTONIANCOMPLETION)

HAMILTONIANCOMPLETION is the following decision problem:

- ▶ Given: undirected graph  $G = \langle V, E \rangle$ , number  $k \in \mathbb{N}_0$
- Question: Can G be extended with at most k edges such that the resulting graph has a Hamilton cycle?

Show that HAMILTONCYCLE  $\leq_p$  HAMILTONIANCOMPLETION.

#### Reminder: P and NP

- P: class of languages that are decidable in polynomial time by a deterministic Turing machine
- NP: class of languages that are decidable in polynomial time by a non-deterministic Turing machine

# Properties of Polynomial Reductions (1)

Theorem (Properties of Polynomial Reductions) Let A, B and C decision problems. a) If  $A \leq_p B$  and  $B \in P$ , then  $A \in P$ . b) If  $A \leq_p B$  and  $B \in NP$ , then  $A \in NP$ . c) If  $A \leq_p B$  and  $A \notin P$ , then  $B \notin P$ . c) If  $A \leq_p B$  and  $A \notin NP$ , then  $B \notin NP$ .

**5** If  $A \leq_p B$  and  $B \leq_p C$ , then  $A \leq_p C$ .

# Properties of Polynomial Reductions (2)

```
Proof.
for 1.:
We must show that there is a DTM deciding A
in polynomial time.
We know:
 \blacktriangleright There is a DTM M_B that decides B in time p.
     where p is a polynomial.
 There is a DTM M<sub>f</sub> that computes a reduction from A to B
     in time q, where q is a polynomial.
                                                                     . . .
```

# Properties of Polynomial Reductions (3)

#### Proof (continued).

Consider the machine M that first behaves like  $M_f$ , and then (after  $M_f$  stops) behaves like  $M_B$  on the output of  $M_f$ .

#### M decides A:

- M behaves on input w as M<sub>B</sub> does on input f(w), so it accepts w if and only if f(w) ∈ B.
- Because f is a reduction,  $w \in A$  iff  $f(w) \in B$ .

. . .

# Properties of Polynomial Reductions (4)

#### Proof (continued).

Computation time of M on input w:

- First  $M_f$  runs on input  $w : \leq q(|w|)$  steps
- then  $M_B$  runs on input f(w):  $\leq p(|f(w)|)$  steps
- |f(w)| ≤ |w| + q(|w|) because in q(|w|) steps,
   M<sub>f</sub> can write at most q(|w|) additional symbols onto the tape
- $\stackrel{\rightsquigarrow}{\to} \text{ total computation time } \leq q(|w|) + p(|f(w)|) \\ \leq q(|w|) + p(|w| + q(|w|))$
- $\rightsquigarrow$  this is polynomial in  $|w| \rightsquigarrow A \in P$ .

. . .

# Properties of Polynomial Reductions (5)

```
Proof (continued).
for 2.:
analogous to 1., only that M_B and M are NTMs
of 3.+4.:
equivalent formulations of 1.+2. (contraposition)
of 5.:
Let A \leq_{p} B with reduction f and B \leq_{p} C with reduction g.
Then g \circ f is a reduction of A to C.
The computation time of the two computations in sequence
is polynomial by the same argument used in the proof for 1.
```

# D2.2 NP-Hardness and NP-Completeness

D2. Polynomial Reductions and NP-completeness

#### NP-Hardness and NP-Completeness

#### Definition (NP-Hard, NP-Complete)

Let B be a decision problem.

*B* is called NP-hard if  $A \leq_p B$  for all problems  $A \in NP$ .

*B* is called NP-complete if  $B \in NP$  and *B* is NP-hard.

# NP-Complete Problems: Meaning

- NP-hard problems are "at least as difficult" as all problems in NP.
- NP-complete problems are "the most difficult" problems in NP: all problems in NP can be reduced to them.
- If A ∈ P for any NP-complete problem A, then P = NP. (Why?)
- That means that either there are efficient algorithms for all NP-complete problems or for none of them.
- Do NP-complete problems actually exist?

# D2.3 Summary

Gabriele Röger (University of Basel)

Theory of Computer Science

May 3, 2023 20 / 21

# Summary

- ▶ polynomial reductions: A ≤<sub>p</sub> B if there is a total function f computable in polynomial time, such that for all words w: w ∈ A iff f(w) ∈ B
- $A \leq_p B$  implies that A is "at most as difficult" as B
- polynomial reductions are transitive
- ▶ NP-hard problems  $B: A \leq_p B$  for all  $A \in NP$
- ▶ NP-complete problems B:  $B \in NP$  and B is NP-hard
