Algorithms and Data Structures

March 27/April 3, 2024 — B1. Arrays and Linked Lists

B1.1 Data Structures

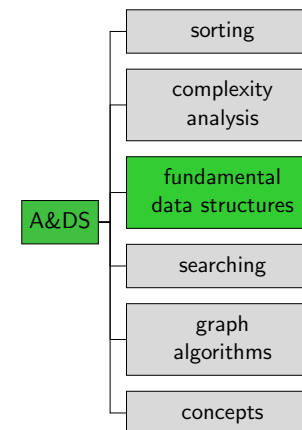

B1.2 Arrays

B1.3 Linked Lists

B1.4 Summary

B1.1 Data Structures

Content of the Course

Data Structures

- ▶ Programming goes beyond writing algorithms.
 - ▶ Organisation of data is central.
- ▶ Elegant data structures lead to elegant code.
- ▶ Programmers. . .
 - ▶ need a catalogue of data structures, and
 - ▶ need to know their characteristics.

Overview

Data Structures

Bad programmers worry about the code. Good programmers worry about data structures and their relationships.

Linus Torwalds

Data Structures

Show me your algorithm and conceal your data structures, and I shall continue to be mystified.

Show me your data structures, and I won't usually need your algorithm; it will be obvious.

Fred Brooks (paraphrased)

B1.2 Arrays

Data Structure: Array

- ▶ **Arrays** are one of the fundamental data structures, that can be found in (almost) every programming language.
- ▶ An array stores a sequence of elements (of the same memory size) as a contiguous sequence of bytes in memory.
- ▶ The number of elements is fixed.
- ▶ We can access elements by their index.

In Java:

```
byte[] myByteArray = new byte[100];
char[] myCharArray = new char[50];
```

Example: char Array

- ▶ One char occupies 1 byte.
- ▶ The first element is at memory address 2000 (7D0 in hexadecimal).
- ▶ The first element has index 0.
- ▶ Then the element with index i is at address $2000 + i$.

Memory address (hex)	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010
(hex)	0x7D0	0x7D1	0x7D2	0x7D3	0x7D4	0x7D5	0x7D6	0x7D7	0x7D8	0x7D9	0x7DA
	h	e	l	l	o	-	w	o	r	l	d
Index	0	1	2	3	4	5	6	7	8	9	10

Array: Position of i -th Element Easy to Compute

In general:

- ▶ First position typically indexed with 0 or 1.
In the following, s for the index of the first element.
- ▶ Suppose the array starts at memory address a and each array element occupies b bytes.
- ▶ Then the element with index i occupies bytes $a + b(i - s)$ to $a + b(i - s + 1) - 1$.

With 32-bit integers (4 byte)

Memory address (hex)	2000	2001	2002	2003	2004	2005	2006	2007
(hex)	0x7D0	0x7D1	0x7D2	0x7D3	0x7D4	0x7D5	0x7D6	0x7D7
	42				23			
Index	0				1			

Operations and their Running Time?

- ▶ Size of entry is constant for a specific array type (such as an int array).
- ▶ After allocating the memory, the array stores
 - ▶ the size of the array (number of elements) and
 - ▶ the address of the start of the allocated memory.
- ▶ What is the running time of the following operations (relative to the size n of the array)?
 - ▶ `get(i)` – return element at position $i \rightsquigarrow \Theta(1)$
 - ▶ `set(i, x)` – write object x to position $i \rightsquigarrow \Theta(1)$
 - ▶ `length()` – return length of the array $\rightsquigarrow \Theta(1)$
 - ▶ `find(x)` – return index of element x or None if not included.
 - \rightsquigarrow iterates over the array and stops if element found.
 - \rightsquigarrow Best case $\Theta(1)$, Avg. and worst case $\Theta(n)$
- ▶ What is the memory complexity?

Observation

Complexity is direct consequence of data representation.

Lists in Python

- ▶ Python lists can contain arbitrarily mixed objects.
 - e.g. `["word", 42, ([39, "hi"])]`
 - ▶ Elements “live” somewhere else in memory.
 - ▶ The memory range of the array only stores their address.
- ▶ Python lists do not have a fixed size.
 - e.g. `["word", 42, ([39, "hi"])] .append(3)`
 - **dynamic array**

Dynamic Arrays

(Static) arrays have fixed capacity that must be specified at allocation.

- ▶ Need arrays that can grow dynamically.
- ▶ Runtime complexity of previous operations should be preserved.

Additional operations:

- ▶ `append(x)` (or `push`) – append element x at the end.
- ▶ `insert(i, x)` – insert element x at position i .
- ▶ `pop()` – remove the last element.
- ▶ `remove(i)` – remove the element at position i .

Changing the Array Size: Naive Method

- ▶ `append` (and `insert`) increase the size of the array.
- ▶ `pop` decreases the size.
- ▶ Naive method:
 - ▶ Allocate new memory range that is one element larger/smaller.
 - ▶ Move all (but the potentially popped) element over.

With this approach, these operations would take linear time in the current size of the array!

Better Approach: Overallocate Memory

- ▶ Allocate more memory than needed for the current array size.
- ▶ Distinguish
 - ▶ **capacity** = number of elements that fit in the allocated space.
 - ▶ **size** = number of currently contained elements.

Better Approach: Append/Insert

Append

- ▶ If $\text{capacity} > \text{size}$:
 - ▶ Write the new element to position size and increment size .
- ▶ Otherwise ($\text{capacity} = \text{size}$):
 - ▶ Allocate new memory that is larger than necessary (e.g. twice the previous capacity).
 - ▶ Copy all elements to the new memory (release the old one).
 - ▶ Update the capacity and continue as in case $\text{capacity} > \text{size}$.

Insert at pos i : Analogously but move all elements at positions i to $\text{size}-1$ one position to the right before writing the new element to i .

Better Approach: Pop/Remove

- ▶ If capacity much too large (e.g. $\text{capacity} > 4 \cdot \text{size}$), move all elements into new smaller memory range (e.g. with half the previous capacity)
- ▶ Pop: remove element at position $\text{size} - 1$ and decrement size .
- ▶ Remove: remove element at position i and move all elements right of i one position to the left, decrement size .

Amortized Analysis

- ▶ Worst-case analysis often pessimistic: append takes linear time if new memory allocated but in a sequence of append operations, this will happen rarely.
- ▶ **Amortized analysis** determines the average cost of an operation over an entire sequence of operations.
- ▶ Don't confuse this with an average-case analysis.
- ▶ Different methods
 - ▶ Aggregate analysis
 - ▶ Accounting method ← now
 - ▶ Potential method

Accounting Method

- ▶ Assign charges to operations.
- ▶ Some operations charged more or less than they actually cost.
- ▶ If charged more: save difference as credit
- ▶ If charged less: use up some credit to pay for the difference.
- ▶ Credit must be non-negative all the time.
- ▶ Then the total amortized cost is always an upper bound on the actual total costs so far.

Accounting Method: Append I

- ▶ Append without resize: constant cost (e.g. 1).
Just insert the element at the right position.
- ▶ Append with resize: linear cost (1 for every element).
 - ▶ If the append element gets position 2^i ($i \in \mathbb{N}_{>0}$),
 - ▶ we first allocate overall space for 2^{i+1} elements, and
 - ▶ move all $2^i - 1$ existing elements to the new space.
- ▶ Starting from an empty array executing a sequence of append operations, we observe cost sequence
1, 1, 3, 1, 5, 1, 1, 1, 9, 1, 1, 1, 1, 1, 1, 1, 1, 17, 1 ...

Accounting Method: Append II

Charge cost 3 for every append operation.

size (after append)	capacity	charge	cost	credit
1	2	3	1	2
2	2	3	1	4
3	4	3	3	4
4	4	3	1	6
5	8	3	5	4
6	8	3	1	6
7	8	3	1	8
8	8	3	1	10
9	16	3	9	4
10	16	3	1	6

Charging 3 per operation covers all “running time costs”.
→ Append has constant amortized running time.

Worst-Case Running Time Array

Operation	Array
Access element by position	$O(1)$
Prepend/remove first element	$O(n)$
Append	$O(1)$ (amortized)
Remove last element	$O(1)$ (amortized)
Insert, remove from the middle	$O(n)$
Traverse all elements	$O(n)$

B1.3 Linked Lists

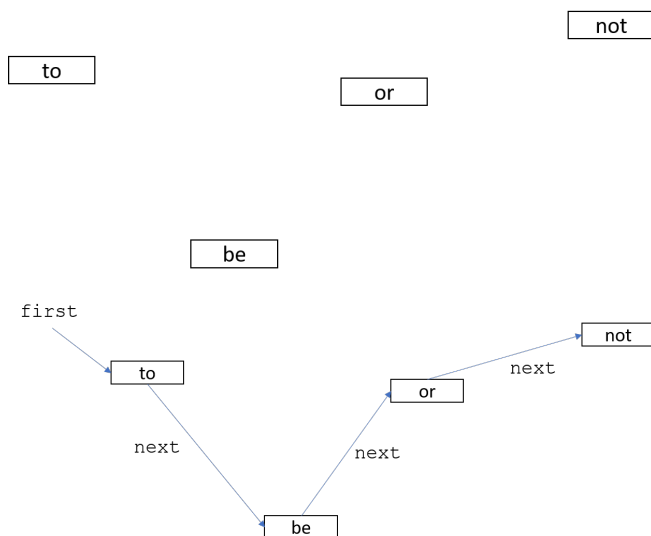

Motivation

- ▶ Arrays need a large continuous block of memory.
- ▶ Inserting elements at arbitrary positions is expensive.

Alternative that allows us to distribute the elements in memory?

Question?

- ▶ How can we order elements that are distributed in memory?

Linked Lists

- ▶ Every node stores its entry as well as a reference (pointer) to its successor.
- ▶ Need special value for the next pointer of the last element.
- ▶ ... or a reference to the last element.

Jupyter Notebook

Jupyter notebook: linked_lists.ipynb

Implementation: Node

```

1 class Node:
2     def __init__(self, item, next=None):
3         self.item = item
4         self.next = next

```

Implementation: List (without last reference)

```

1 class LinkedList:
2     def __init__(self):
3         self.first = None
4
5     # prepend item at the front of the list
6     def prepend(self, item):
7         new_node = Node(item, self.first)
8         self.first = new_node
9
10    ... # other methods added to notebook after lecture

```

Worst-Case Running Time Array / Linked List

Operation	Array	Linked List
Prepend/remove first element	$O(n)$	$O(1)$
Append	$O(1)$ (amortized)	$O(n)$
Remove last element	$O(1)$ (amortized)	$O(n)$
Insert, remove from the middle	$O(n)$	$O(n)$
Traverse all elements	$O(n)$	$O(n)$
Find an element	$O(n)$	$O(n)$
Access element by position	$O(1)$	–

What running times could we improve if we also maintained a pointer to the last element of the linked list?

Take-home Message

- ▶ Different data structures have different trade-offs.

Doubly Linked Lists

- ▶ Idea: Do not only store a reference to the successor but also to the predecessor.
- ▶ Renders appending at/removal from end constant time.

Jupyter Notebook

Jupyter notebook: doubly_linked_lists.ipynb

Doubly Linked Lists: Implementation

```

1 class Node:
2     def __init__(self, item, next=None):
3         self.item = item
4         self.next = next
5
6 class DoublyLinkedList:
7     def __init__(self):
8         self.first = None
9         self.last = None
10
11     def is_empty(self):
12         return self.first is None
13
14     # other methods on next slides

```

Doubly Linked Lists: prepend

```

15 def prepend(self, item):
16     if self.is_empty():
17         self.first = Node(item)
18         self.last = self.first
19     else:
20         node = Node(item, self.first, None)
21         self.first.prev = node
22         self.first = node

```

Doubly Linked Lists: append

```

24     def append(self, item):
25         if self.is_empty():
26             self.first = Node(item)
27             self.last = self.first
28         else:
29             node = Node(item, None, self.last)
30             self.last.next = node
31             self.last = node

```

Doubly Linked Lists: remove_first

```

33     def remove_first(self):
34         if self.is_empty():
35             raise Exception("removing from empty list")
36         item = self.first.item
37         self.first = self.first.next
38         if self.first is not None:
39             self.first.prev = None
40         else:
41             self.last = None
42         return item

```

Doubly Linked Lists: remove_last

With doubly linked lists, removing the last element is analogous to removing the first element:

```

44     def remove_last(self):
45         if self.is_empty():
46             raise Exception("removing from empty list")
47         item = self.last.item
48         self.last = self.last.prev
49         if self.last is not None:
50             self.last.next = None
51         else:
52             self.first = None
53         return item

```

Worst-Case Running Time Array / Doubly Linked List

Operation	Array	Doubly Linked List
Prepend/remove first element	$O(n)$	$O(1)$
Append	$O(1)$ (amort.)	$O(1)$
Remove last element	$O(1)$ (amort.)	$O(1)$
Insert, remove in the middle	$O(n)$	$O(n)/O(1)^*$
Traverse all elements	$O(n)$	$O(n)$
Find an element	$O(n)$	$O(n)$
Access element by position	$O(1)$	–

* constant, if node at the position is parameter

Take-home Message

Compared to singly linked lists, doubly linked lists need a linear amount of additional memory (for the prev references), but provide better running times for operations at the end of the list.

B1.4 Summary

Summary

- ▶ An **amortized analysis** determines the average cost of an operation over an entire sequence of operations.
- ▶ Arrays and linked lists store sequences of items.
 - ▶ **Arrays** store items in a continuous space and can efficiently access an item by index.
 - ▶ **Linked lists** store items in nodes with a reference to the next node (**doubly linked lists**: also to previous node).
