# Reminder: Graph Exploration

- $\triangleright$  Given a vertex v, visit all vertices that are reachable from v.
- ▶ Often used as part of other graph algorithms.
- ▶ Depth-first search: go "deep" into the graph (away from v)
- ▶ Breadth-first search: first all neighbours, then neighbours of neighbours, ...

Reachability

# Mark-and-Sweep Garbage Collection

Aim: Release memory occupied by no longer accessible objects.

- ▶ Directed graph: Objects as vertices, references to objects as edges.
- ▶ One bit per object for marker during garbage collection.
- Mark: Mark all reachable objects (set bit to 1).
- ➤ Sweep: Clear unmarked objects from memory.

  Afterwards set bit for all reachable objects back to 0.

Shortest Paths

12 / 40

#### Shortest Paths: Idea

- ► Breadth-first search visits the vertices with increasing (minimal) distance from the start vertex.
- First visit of a vertex happens on shortest path.
- ▶ Idea: Use path from induced search tree.

 ${\tt Jupyter\ notebook:\ graph\_exploration\_applications.ipynb}$

Shortest Paths

## Shortest-path Problem

#### Single-source Shortest-paths Problem

- ► Given: Graph and start vertex s
- Query for vertex v
  - ▶ Is there a path from s to v?
  - ► If yes, what is the shortest path?
- ► Abbreviation SSSP

G. Röger (University of Basel)

Acvelic Graphs

## Topological Sort

#### Definition

A topological sort of a directed acyclic graph G = (V, E) is a linear ordering of all its vertices such that if G contains an edge (u, v), then u appears before v in the ordering.

For example relevant for scheduling: edge (u, v) expresses that job u must be completed before job v can be started.

C2. Graph Exploration: Applications

Acyclic Granhs

# Topological Sort: Algorithm

#### Theorem

For the reachable part of a acyclic graph, the reverse DFS postorder is a topological sort.

#### Algorithm:

- Sequence of depth-first searches (for still unvisited vertices) until all vertices visited.
- ► Store for each DFS the reverse postorder: P<sub>i</sub> for i-th search
- Let k be the number of searches. Then the concatenation  $P_k, \ldots, P_1$  is a topological sort.

#### Kosaraju' algorithm

- ▶ Given directed graph G = (V, E), compute a reverse postorder P (for all vertices) of the graph  $G^R = (V, \{(v, u) \mid (u, v) \in E\})$  (all edges reversed).
- ► Conduct a sequence of explorations in *G*, always selecting the first still unvisited vertex in *P* as the next start vertex.
- ► All vertices that are reached by the same exploration, are in the same strongly connected component.

## Summary

We have seen a number of applications of graph exploration:

- Reachability
- ► Shortest paths
- ► Cycle detection
- ► Topological sort
- Connected components

Some applications require a specific exploration, for other applications we can use both, BFS and DFS.
