Seam Carving

What are we interested in?

► Single source: from one vertex s to all other vertices

► Single sink: from all vertices to one vertex t

► Source-sink: from vertex s to vertex t

► All pairs: from every vertex to every vertex

Graph properties

G. Röger (University of Basel)

- ▶ arbitrary / non-negative / Euclidean weights
- ► arbitrary / non-negative / no cycles

Algorithms and Data Structures

C5. Shortest Paths: Foundations Introduction

Applications

- ► Route planning
- ► Path planning in games
- ► robot navigation
- seam carving
- automated planning
- typesetting in TeX
- routing protocols in networks (OSPF, BGP, RIP)
- routing of telecommunication messages
- ► traffic routing

C5. Shortest Paths: Foundations

Same (high-level) definition of weighted graphs as before, but now we consider directed graphs.

Directed Graph

Weighted Directed Graphs

An (edge)-weighted graph associates every edge e with a weight (or cost) $weight(e) \in \mathbb{R}$.

Reminder: A directed graphs is also called a digraph.

API for Weighted Directed Edge

```
class DirectedEdge:
       # Edge from n1 to n2 with weight w
       def __init__(n1: int, n2: int, w: float) -> None
3
4
       # Weight of the edge
5
       def weight() -> float
6
7
8
       # Initial vertex of the edge
       def from_node() -> int
9
10
       # Terminal vertex of the edge
11
       def to node() -> int
12
```

Algorithms and Data Structures

API for Weighted Digraphs

```
class EdgeWeightedDigraph:
       # Graph with no_nodes vertices and no edges
       def __init__(no_nodes: int) -> None
       # Add weighted edge
       def add_edge(e: DirectedEdge) -> None
       # Number of vertices
       def no_nodes() -> int
10
       # Number of edges
11
       def no_edges() -> int
12
13
       # All outgoing edges of n
14
       def outgoing_edges(n: int) -> Generator[DirectedEdge]
15
16
17
       # All edges
       def all_edges() -> Generator[DirectedEdge]

Shortest Path Problem

Single-source shortest path problem, SSSP

- ► Given: Graph and start vertex s
- Query for vertex v
 - ▶ Is there a path from s to v?
 - ► If yes, what is the shortest path?
- ► In weighted graphs: Shortest path is the one with lowest weight (= minimal sum of edge costs)

C5. Shortest Paths: Foundations

Foundati

API for Shortest-path Implementation

The algorithms for shortest paths should implement the following interface:

```
1 class ShortestPaths:
2  # Initialization for start vertex s
3  def __init__(graph: EdgeWeightedDigraph, s: int) -> None
4
5  # Distance from s to v; infinity, if there is no path
6  def dist_to(v: int) -> float
7
8  # Is there a path from s to v?
9  def has_path_to(v: int) -> bool
10
11  # Path from s to v; None, if there is none
12  def path_to(v: int) -> Generator[DirectedEdge]
```

Foundations

Shortest-path Tree

Shortest-path Tree

For a weighted digraph G and vertex s, a shortest-path tree is a subgraph that

- forms a directed tree with root s.
- contains all vertices that are reachable from s, and
- \triangleright for which every path in the tree is a shortest path in G.

C5. Shortest Paths: Foundations

Foundations

Shortest-path Tree: Representation

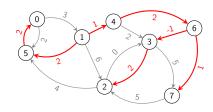

Representation: arrays indexed by vertex

- parent with reference to parent vertex
 None for unreachable vertices and start vertex
- distance with distance from the start vertex of for unreachable vertices

```
parent 5 None 3 6 1 1 4 6

0 1 2 3 4 5 6 7
```

0 1 2 3 4 5 6 7

What about parallel edges?

Extracting Shortest Paths

```
def path_to(self, node):
    if self.distance[node] == float('inf'):
        yield None
    elif self.parent[node] is None:
        yield node
    else:
        # output path from start to parent node
        self.path_to(self.parent[node])
        # finish with node
        yield node
```

This implementation generates a sequence of vertices. What do we have to change to generate a corresponding sequence of edges?

Relaxation

Relaxing edge (u, v)

- ightharpoonup distance[u]: cost of the shortest known path to u
- ▶ distance[v]: cost of the shortest known path to v
- parent[v]: predecessor of v in the shortest known paths to v
- ▶ Does edge (u, v) establish a shorter path to v (through u)?
- ▶ If yes, update distance[v] and parent[v].

Optimality Criterion and Generic Algorithm

Optimality Criterion

Theorem

Let G be a weighted digraph without negative cycles.

Array distance[] contains the cost of the shortest paths from s if and only if

- $\mathbf{0}$ distance[s] = $\mathbf{0}$
- ② $distance[w] \le distance[v] + weight(e)$ for all edges e = (v, w), and
- for all vertices v, distance[v] is the cost of some path from s to v, or ∞ if there is no such path.

G. Röger (University of Basel)

Algorithms and Data Structures

May 22, 2024

21 / 26

C5. Shortest Paths: Foundations

Optimality Criterion and Generic Algorithm

Optimality Criterion (Continued)

Proof "⇒"

- Since the graph has no cycles of negative cost, no path from s to s can have negative cost. Thus, the empty path is optimal and distance[s] is 0.
- ② Consider an arbitrary edge e from u to v.

 The shortest path from s to u has cost distance[u]. If we extend this path by edge e, we have a path from s to v of cost distance[u] + weight(e). Thus, the cost of a shortest path from s to v cannot be larger and it holds that distance[v] \leq distance[u] + weight(e).
- Trivially true.

C5. Shortest Paths: Foundations

Optimality Criterion and Generic Algorithm

Optimality Criterion (Continued)

Proof (continued).

"←

For unreachable vertices, the value is infinity by definition.

Consider an arbitrary vertex v and a shortest path $p = (v_0, \dots, v_n)$ from s to v, i.e. $v_0 = s$, $v_n = v$.

For $i \in \{1, ..., n\}$, let e_i be a cheapest edge from v_{i-1} to v_i . Since all inequalities are satisfied, we have

$$ext{distance}[v_n] \leq ext{distance}[v_{n-1}] + weight(e_n)$$
 $ext{ } \leq ext{distance}[v_{n-2}] + weight(e_{n-1}) + weight(e_n)$
 $ext{ } \leq \ldots \leq weight(e_1) + \cdots + weight(e_n)$
 $ext{ } = ext{cost of an optimal path.}$

Due to 3, distance $[v_n]$ cannot be lower than the optimal cost. \square

C5. Shortest Paths: Foundations

Optimality Criterion and Generic Algorithm

Generic Algorithm

Generic Algorithm for Start Vertex s

- Initialize distance[s] = 0 and distance[v] = ∞ for all other vertices
- As long as the optimality criterion is not satisfied: Relax an arbitrary edge

Correct:

- ► Finite distance[v] always corresponds to the cost of a path from s to v.
- ► Every successful relaxation reduces distance[v] for some v.
- ► For every vertex, the distance can only be reduced finitely often.

Summany

Summary

➤ Single-source shortest paths: Compute in a weighted digraph the shortest paths from a given vertex to all reachable vertices.

► Relaxation: If for edge (u,v) the best known distance to v is larger than the one to u plus the edge cost, then update the distance to v (with predecessor u).

► Generic algorithm

- ▶ Based on relaxation and optimality criterion.
- ► Every instantiation is correct for all weighted digraphs without negative-cost cycles.
- ► Specific instantiations: next chapter.
