# State-Space Search: Overview

## Chapter overview: state-space search

- B1–B3. Foundations
- B4–B8. Basic Algorithms
  - B4. Data Structures for Search Algorithms
  - B5. Tree Search and Graph Search
  - B6. Breadth-first Search
  - B7. Uniform Cost Search
  - B8. Depth-first Search and Iterative Deepening
- B9–B15. Heuristic Algorithms

# Depth-first Search

# Idea of Depth-first Search

## depth-first search:

- expands nodes in **opposite order of generation** (LIFO)
- open list implemented as **stack**

↪ **deepest** node expanded first

German: Tiefensuche

# Depth-first Search Example

# Depth-first Search: Some Properties

- almost always implemented as a **tree search** (we will see why)
- **not complete, not semi-complete, not optimal** (Why?)
- complete for **acyclic** state spaces,  
e.g., if state space directed tree

# Reminder: Generic Tree Search Algorithm

reminder from Chapter B5:

## Generic Tree Search

```
open := new OpenList
open.insert(make_root_node())
while not open.is_empty():
    n := open.pop()
    if is_goal(n.state):
        return extract_path(n)
    for each  $\langle a, s' \rangle \in$  succ(n.state):
        n' := make_node(n, a, s')
        open.insert(n')
return unsolvable
```

# Depth-first Search (Non-recursive Version)

depth-first search (non-recursive version):

## Depth-first Search (Non-recursive Version)

```
open := new Stack
open.push_back(make_root_node())
while not open.is_empty():
    n := open.pop_back()
    if is_goal(n.state):
        return extract_path(n)
    for each  $\langle a, s' \rangle \in$  succ(n.state):
        n' := make_node(n, a, s')
        open.push_back(n')
return unsolvable
```

# Non-recursive Depth-first Search: Discussion

## discussion:

- there isn't much wrong with this pseudo-code  
(as long as we ensure to release nodes that are no longer required  
when using programming languages without garbage collection)
- however, depth-first search as a **recursive algorithm**  
is simpler and more efficient
- ↪ CPU stack as implicit open list
- ↪ no search node data structure needed

# Depth-first Search (Recursive Version)

```
function depth_first_search(s)  
if is_goal(s):  
    return ⟨⟩  
for each ⟨a, s'⟩ ∈ succ(s):  
    solution := depth_first_search(s')  
    if solution ≠ none:  
        solution.push_front(a)  
    return solution  
return none
```

main function:

## Depth-first Search (Recursive Version)

```
return depth_first_search(init())
```

# Depth-first Search: Complexity

## time complexity:

- If the state space includes paths of length  $m$ , depth-first search can generate  $O(b^m)$  nodes, even if much shorter solutions (e.g., of length 1) exist.
- On the other hand: in the **best case**, solutions of length  $\ell$  can be found with  $O(b\ell)$  generated nodes. (Why?)
- improvable to  $O(\ell)$  with **incremental successor generation**

# Depth-first Search: Complexity

## time complexity:

- If the state space includes paths of length  $m$ , depth-first search can generate  $O(b^m)$  nodes, even if much shorter solutions (e.g., of length 1) exist.
- On the other hand: in the **best case**, solutions of length  $\ell$  can be found with  $O(b\ell)$  generated nodes. (Why?)
- improvable to  $O(\ell)$  with **incremental successor generation**

## space complexity:

- only need to store nodes **along currently explored path** (“along”: nodes on path and their children)
- ↪ space complexity  $O(bm)$  if  $m$  maximal search depth reached
- low memory complexity main reason why depth-first search interesting despite its disadvantages

# Iterative Deepening

# Idea of Depth-limited Search

## depth-limited search:

- parameterized with **depth limit**  $\ell \in \mathbb{N}_0$
- behaves like depth-first search, but **prunes** (does not expand) search nodes at depth  $\ell$
- not very useful on its own, but **important ingredient** of more useful algorithms

**German:** tiefenbeschränkte Suche

# Depth-limited Search Example

Consider depth limit  $\ell = 2$ .

# Depth-limited Search: Pseudo-Code

```
function depth_limited_search(s, depth_limit):
```

```
  if is_goal(s):
```

```
    return  $\langle \rangle$ 
```

```
  if depth_limit > 0:
```

```
    for each  $\langle a, s' \rangle \in \text{succ}(s)$ :
```

```
      solution := depth_limited_search(s', depth_limit - 1)
```

```
      if solution  $\neq$  none:
```

```
        solution.push_front(a)
```

```
        return solution
```

```
return none
```

# Iterative Deepening Depth-first Search

## iterative deepening depth-first search (iterative deepening DFS):

- **idea:** perform a sequence of depth-limited searches with increasing depth limit
- sounds wasteful (each iteration repeats all the useful work of all previous iterations)
- in fact overhead acceptable ( $\rightsquigarrow$  analysis follows)

### Iterative Deepening DFS

```
for depth_limit  $\in$  {0, 1, 2, ... }:  
    solution := depth_limited_search(init(), depth_limit)  
    if solution  $\neq$  none:  
        return solution
```

**German:** iterative Tiefensuche

# Example

depth limit: 0

generated nodes: 1

# Example

depth limit: 1

generated nodes: 1+3

# Example

depth limit: 2

generated nodes: 1+3+7

# Example

depth limit: 3

generated nodes:  $1+3+7+9=20$

# Iterative Deepening DFS: Properties

combines advantages of breadth-first and depth-first search:

- (almost) like BFS: semi-complete (however, not complete)
- like BFS: optimal if all actions have same cost
- like DFS: only need to store nodes along one path  
↪ space complexity  $O(bd)$ , where  $d$  minimal solution length
- time complexity only slightly higher than BFS  
(↪ analysis soon)

# Iterative Deepening DFS: Complexity Example

time complexity (generated nodes):

breadth-first search	$1 + b + b^2 + \dots + b^{d-1} + b^d$
iterative deepening DFS	$(d + 1) + db + (d - 1)b^2 + \dots + 2b^{d-1} + 1b^d$

example:  $b = 10$ ,  $d = 5$

breadth-first search	$1 + 10 + 100 + 1000 + 10000 + 100000$ $= 111111$
iterative deepening DFS	$6 + 50 + 400 + 3000 + 20000 + 100000$ $= 123456$

for  $b = 10$ , only 11% more nodes than breadth-first search

# Iterative Deepening DFS: Time Complexity

## Theorem (time complexity of iterative deepening DFS)

Let  $b$  be the branching factor and  $d$  be the minimal solution length of the given state space. Let  $b \geq 2$ .

Then the **time complexity** of iterative deepening DFS is

$$(d + 1) + db + (d - 1)b^2 + (d - 2)b^3 + \dots + 1b^d = O(b^d)$$

and the **memory complexity** is

$$O(bd).$$

# Iterative Deepening DFS: Evaluation

## Iterative Deepening DFS: Evaluation

Iterative Deepening DFS is often the method of choice if

- **tree search is adequate** (no duplicate elimination necessary),
- all **action costs** are identical, and
- the **solution depth** is **unknown**.

# Summary

# Summary

**depth-first search:** expand nodes in **LIFO** order

- usually as a **tree search**
- easy to implement **recursively**
- very **memory-efficient**
- can be combined with **iterative deepening**  
to combine many of the good aspects  
of breadth-first and depth-first search

# Comparison of Blind Search Algorithms

completeness, optimality, time and space complexity

criterion	search algorithm				
	breadth- first	uniform cost	depth- first	depth- limited	iterative deepening
complete?	yes*	yes	no	no	semi
optimal?	yes**	yes	no	no	yes**
time	$O(b^d)$	$O(b^{\lfloor c^*/\epsilon \rfloor + 1})$	$O(b^m)$	$O(b^\ell)$	$O(b^d)$
space	$O(b^d)$	$O(b^{\lfloor c^*/\epsilon \rfloor + 1})$	$O(bm)$	$O(b\ell)$	$O(bd)$

- $b \geq 2$  branching factor
- $d$  minimal solution depth
- $m$  maximal search depth
- $\ell$  depth limit
- $c^*$  optimal solution cost
- $\epsilon > 0$  minimal action cost

remarks:

- \* for BFS-Tree: semi-complete
- \*\* only with uniform action costs
