Introduction

#### Optimality of A\* without Reopening

We now study A\* without reopening.

- ► For A\* without reopening, admissibility and consistency together guarantee optimality.
- ► We prove this on the following slides, again beginning with a basic lemma.
- ► Either of the two properties on its own would not be sufficient for optimality. (How would one prove this?)

Introduction

#### Reminder: A\* without Reopening

#### reminder from Chapter B11/B12: A\* without reopening

```
A* without Reopening
open := new MinHeap ordered by \langle f, h \rangle
if h(\text{init}()) < \infty:
     open.insert(make_root_node())
closed := new HashSet
while not open.is_empty():
     n := open.pop_min()
     if n.state ∉ closed:
           closed.insert(n)
           if is_goal(n.state):
                return extract_path(n)
           for each \langle a, s' \rangle \in \text{succ}(n.\text{state}):
                if h(s') < \infty:
                      n' := \mathsf{make\_node}(n, a, s')
                      open.insert(n')
return unsolvable
```

Monotonicity Lemma

March 31, 2025

## A\*: Monotonicity Lemma (1)

```
Lemma (monotonicity of A* with consistent heuristics)
```

Consider A\* with a consistent heuristic.

Then:

- If n' is a child node of n, then  $f(n') \ge f(n)$ .
- On all paths generated by A\*, f values are non-decreasing.
- The sequence of f values of the nodes expanded by A\* is non-decreasing.

German: Monotonielemma

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

March 31, 2025

#### A\*: Monotonicity Lemma (2)

Proof.

on 1.:

Let n' be a child node of n via action a.

Let s = n.state. s' = n'.state.

- $\blacktriangleright$  by definition of f: f(n) = g(n) + h(s), f(n') = g(n') + h(s')
- by definition of g: g(n') = g(n) + cost(a)
- $\blacktriangleright$  by consistency of h: h(s) < cost(a) + h(s')
- $\rightarrow f(n) = g(n) + h(s) \le g(n) + cost(a) + h(s')$ = g(n') + h(s') = f(n')

on 2.: follows directly from 1.

B15. State-Space Search: Properties of A\*, Part II

## A\*: Monotonicity Lemma (3)

Proof (continued).

on 3:

- $\triangleright$  Let  $f_b$  be the minimal f value in open at the beginning of a while loop iteration in A\*. Let *n* be the removed node with  $f(n) = f_b$ .
- to show: at the end of the iteration the minimal f value in open is at least  $f_h$ .
- ▶ We must consider the operations modifying *open*: open.pop\_min and open.insert.
- open.pop\_min can never decrease the minimal f value in open (only potentially increase it).
- ightharpoonup The nodes n' added with open.insert are children of nand hence satisfy  $f(n') \ge f(n) = f_b$  according to part 1.

Optimality of A\* without Reopening

## Optimality of A\* without Reopening

Theorem (optimality of A\* without reopening)

A\* without reopening is optimal when using an admissible and consistent heuristic.

Proof.

From the monotonicity lemma, the sequence of f values of nodes removed from the open list is non-decreasing.

- $\rightarrow$  If multiple nodes with the same state s are removed from the open list, then their g values are non-decreasing.
- → If we allowed reopening, it would never happen.
- → With consistent heuristics, A\* without reopening behaves the same way as A\* with reopening.

The result follows because A\* with reopening and admissible heuristics is optimal.

B15. State-Space Search: Properties of A\*, Part II

## Time Complexity of A\* (1)

#### What is the time complexity of A\*?

- depends strongly on the quality of the heuristic
- $\blacktriangleright$  an extreme case: h = 0 for all states
  - → A\* identical to uniform cost search
- ▶ another extreme case:  $h = h^*$  and cost(a) > 0for all actions a
  - → A\* only expands nodes along an optimal solution
  - $\rightarrow$   $O(\ell^*)$  expanded nodes,  $O(\ell^*b)$  generated nodes, where
    - $\blacktriangleright$   $\ell^*$ : length of the found optimal solution
    - b: branching factor

B15. State-Space Search: Properties of A\*, Part II

Time Complexity of A\*

## Time Complexity of A\* (2)

#### more precise analysis:

dependency of the runtime of A\* on heuristic error

#### example:

- unit cost problems with
- constant branching factor and
- ightharpoonup constant absolute error:  $|h^*(s) h(s)| < c$  for all  $s \in S$

#### time complexity:

- ▶ if state space is a tree: time complexity of A\* grows linearly in solution length (Pohl 1969; Gaschnig 1977)
- ▶ general search spaces: runtime of A\* grows exponentially in solution length (Helmert & Röger 2008)

B15. State-Space Search: Properties of A\*, Part II

Time Complexity of A\*

#### Overhead of Reopening

#### How does reopening affect runtime?

- ▶ For most practical state spaces and inconsistent admissible heuristics, the number of reopened nodes is negligible.
- exceptions exist: Martelli (1977) constructed state spaces with n states where exponentially many (in n) node reopenings occur in  $A^*$ . (→ exponentially worse than uniform cost search)

#### Summary

- ► A\* without reopening using an admissible and consistent heuristic is optimal
- key property monotonicity lemma (with consistent heuristics):
  - ► f values never decrease along paths considered by A\*
  - sequence of f values of expanded nodes is non-decreasing
- time complexity depends on heuristic and shape of state space
  - precise details complex and depend on many aspects
  - reopening increases runtime exponentially in degenerate cases, but usually negligible overhead
  - small improvements in heuristic values often lead to exponential improvements in runtime
