Constraint Satisfaction Problems: Overview

Chapter overview: constraint satisfaction problems

- D1–D2. Introduction
- D3–D5. Basic Algorithms
  - D3. Backtracking
  - D4. Arc Consistency
  - D5. Path Consistency
- D6–D7. Problem Structure

D3.1 CSP Algorithms

CSP Algorithms

In the following chapters, we consider algorithms for solving constraint networks.

basic concepts:

- search: check partial assignments systematically
- backtracking: discard inconsistent partial assignments
- inference: derive equivalent, but tighter constraints to reduce the size of the search space

D3.2 Naive Backtracking

Naive Backtracking (= Without Inference)

function NaiveBacktracking($\mathcal{C}, \alpha$):
$\langle V, \text{dom}, (R_{uv}) \rangle := \mathcal{C}$
if α is inconsistent with $\mathcal{C}$:
  return inconsistent
if α is a total assignment:
  return α
select some variable v for which α is not defined
for each $d \in \text{dom}(v)$ in some order:
  $\alpha' := \alpha \cup \{v \mapsto d\}$
  $\alpha'' := \text{NaiveBacktracking}(\mathcal{C}, \alpha')$
  if $\alpha'' \neq$ **inconsistent**:
    return α''
return inconsistent

input: constraint network $\mathcal{C}$ and partial assignment α for $\mathcal{C}$
(first invocation: empty assignment $\alpha = \emptyset$)
result: solution of $\mathcal{C}$ or **inconsistent**

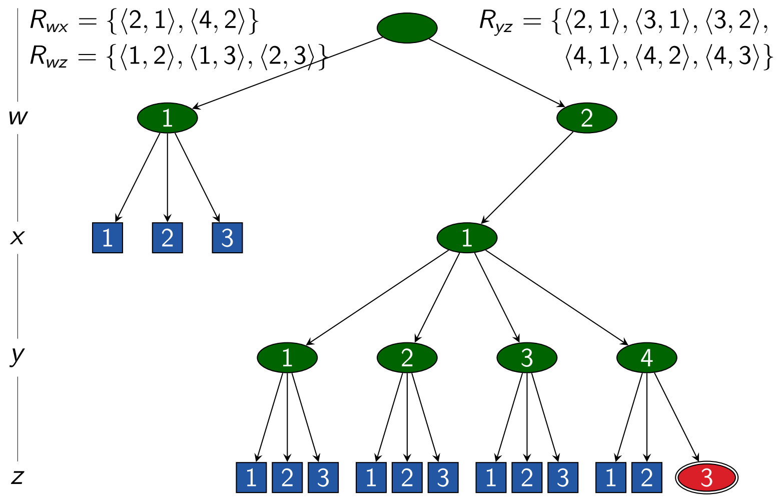
Running Example

Full Formal Model of Running Example

$\mathcal{C} = \langle V, \text{dom}, (R_{uv}) \rangle$ with

- variables:
  $V = \{w, x, y, z\}$
- domains:
  $\text{dom}(w) = \text{dom}(y) = \{1, 2, 3, 4\}$
  $\text{dom}(x) = \text{dom}(z) = \{1, 2, 3\}$
- constraints:
  $R_{wx} = \{\langle 2, 1 \rangle, \langle 4, 2 \rangle\}$
  $R_{wz} = \{\langle 1, 2 \rangle, \langle 1, 3 \rangle, \langle 2, 3 \rangle\}$
  $R_{yz} = \{\langle 2, 1 \rangle, \langle 3, 1 \rangle, \langle 3, 2 \rangle, \langle 4, 1 \rangle, \langle 4, 2 \rangle, \langle 4, 3 \rangle\}$

Running Example: Search Tree



Is This a New Algorithm?

We have already seen this algorithm:
Backtracking corresponds to depth-first search (Chapter B8)
with the following state space:

- states: partial assignments
- initial state: empty assignment $\emptyset$
- goal states: consistent total assignments
- actions: $\mathit{assign}_{v,d}$ assigns value $d \in \mathrm{dom}(v)$ to variable v
- action costs: all 0 (all solutions are of equal quality)
- transitions:
  - for each non-total consistent assignment α, choose variable $v = \mathrm{select}(\alpha)$ that is unassigned in α
  - transition $\alpha \xrightarrow{\mathit{assign}_{v,d}} \alpha \cup \{v \mapsto d\}$ for each $d \in \mathrm{dom}(v)$

Why Depth-First Search?

Depth-first search is particularly well-suited for CSPs:

- path length bounded (by the number of variables)
- solutions located at the same depth (lowest search layer)
- state space is directed tree, initial state is the root
  $\rightsquigarrow$ no duplicates (Why?)

Hence none of the problematic cases for depth-first search occurs.

Naive Backtracking: Discussion

- Naive backtracking often has to exhaustively explore similar search paths (i.e., partial assignments that are identical except for a few variables).
- "Critical" variables are not recognized and hence considered for assignment (too) late.
- Decisions that necessarily lead to constraint violations are only recognized when all variables involved in the constraint have been assigned.

$\rightsquigarrow$ more intelligence by focusing on critical decisions and by inference of consequences of previous decisions

D3.3 Variable and Value Orders

Naive Backtracking

function NaiveBacktracking($\mathcal{C}, \alpha$):
$\langle V, \text{dom}, (R_{uv}) \rangle := \mathcal{C}$
if α is inconsistent with $\mathcal{C}$:
    return inconsistent
if α is a total assignment:
    return α
select some variable v for which α is not defined
for each $d \in \text{dom}(v)$ in some order:
    $\alpha' := \alpha \cup \{v \mapsto d\}$
    $\alpha'' := \text{NaiveBacktracking}(\mathcal{C}, \alpha')$
    if $\alpha'' \neq$ **inconsistent**:
        return α''
return inconsistent

Variable Orders

- Backtracking does not specify in which order variables are considered for assignment.
- Such orders can strongly influence the search space size and hence the search performance.
  ⇝ example: exercises
- Eventually we have to assign all variables
  ⇝ prefer critical assignments (fail early)

German: Variablenordnung

Value Orders

- Backtracking does not specify in which order the values of the selected variable v are considered.
- This is not as important because it does not matter in subtrees without a solution. (Why not?)
- If there is a solution in the subtree, then ideally a value that leads to a solution should be chosen.
  ⇝ prefer promising assignments

German: Werteordnung

Static vs. Dynamic Orders

we distinguish:
- static orders (fixed prior to search)
- dynamic orders (selected variable or value order depends on the search state)

comparison:
- dynamic orders obviously more powerful
- static orders $\rightsquigarrow$ no computational overhead during search

The following ordering criteria can be used statically, but are more effective combined with inference ($\rightsquigarrow$ later) and used dynamically.

Variable Orders

two common variable ordering criteria:
- minimum remaining values:
  prefer variables that have small domains
  - intuition: few subtrees $\rightsquigarrow$ smaller tree
  - extreme case: only one value $\rightsquigarrow$ forced assignment
- most constraining variable:
  prefer variables contained in many nontrivial constraints
  - intuition: constraints tested early
    $\rightsquigarrow$ inconsistencies recognized early $\rightsquigarrow$ smaller tree

combination: use minimum remaining values criterion, then most constraining variable criterion to break ties

Value Orders

Definition (conflict)
Let $\mathcal{C} = \langle V, \mathrm{dom}, (R_{uv}) \rangle$ be a constraint network.
For variables $v \neq v'$ and values $d \in \mathrm{dom}(v)$, $d' \in \mathrm{dom}(v')$,
the assignment $v \mapsto d$ is in conflict with $v' \mapsto d'$ if $\langle d, d' \rangle \notin R_{vv'}$.

value ordering criterion for partial assignment α and selected variable v:
- minimum conflicts: prefer values $d \in \mathrm{dom}(v)$ such that $v \mapsto d$ causes as few conflicts as possible with variables that are unassigned in α

D3.4 Summary

Summary: Backtracking

basic search algorithm for constraint networks: backtracking

- extends the (initially empty) partial assignment step by step until an inconsistency or a solution is found
- is a form of depth-first search
- depth-first search particularly well-suited because state space is directed tree and all solutions at same (known) depth

Summary: Variable and Value Orders

- Variable orders influence the performance of backtracking significantly.
  - goal: critical decisions as early as possible
- Value orders influence the performance of backtracking on solvable constraint networks significantly.
  - goal: most promising assignments first
