Relaxed Planning Graphs

## Relaxed Planning Graphs

- relaxed planning graphs: represent which variables in  $\Pi^+$  can be reached and how
- ightharpoonup graphs with variable layers  $V^i$  and action layers  $A^i$ 
  - ▶ variable layer  $V^0$  contains the variable vertex  $v^0$  for all  $v \in I$
  - ▶ action layer  $A^{i+1}$  contains the action vertex  $a^{i+1}$  for action a if  $V^i$  contains the vertex  $v^i$  for all  $v \in pre(a)$
  - variable layer  $V^{i+1}$  contains the variable vertex  $v^{i+1}$  if previous variable layer contains  $v^i$ , or previous action layer contains  $a^{i+1}$  with  $v \in add(a)$

Relaxed Planning Graphs

## F4. Automated Planning: Delete Relaxation Heuristics

## Illustrative Example

We write actions a with 
$$pre(a) = \{p_1, \dots, p_k\}$$
,  $add(a) = \{q_1, \dots, q_l\}$ ,  $del(a) = \emptyset$  and  $cost(a) = c$  as  $p_1, \dots, p_k \stackrel{c}{\longrightarrow} q_1, \dots, q_l$ 

$$V = \{m, n, o, p, q, r, s, t\}$$

$$I = \{m\}$$

$$G = \{o, p, q, r, s\}$$

$$A = \{a_1, a_2, a_3, a_4, a_5, a_6\}$$

$$a_1 = m \xrightarrow{3} n, o$$

$$a_2 = m, o \xrightarrow{1} p$$

$$a_3 = n, o \xrightarrow{1} q$$

$$a_4 = n \xrightarrow{1} r$$

$$a_5 = p \xrightarrow{1} q, r$$

$$a_6 = p \xrightarrow{1} s$$

F4. Automated Planning: Delete Relaxation Heuristics

Relaxed Planning Graphs

## Relaxed Planning Graphs (Continued)

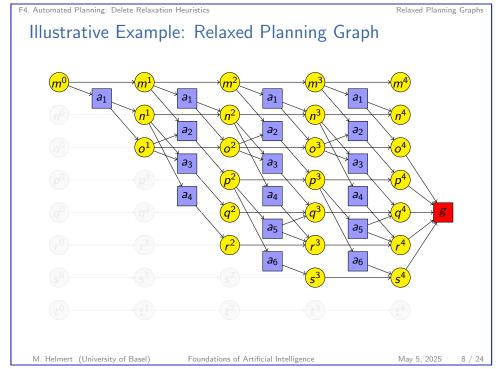

- ▶ a goal vertex g if  $v^n \in V^n$  for all  $v \in G$ , where n is last layer
- ▶ graph can be constructed for arbitrary many layers but stabilizes after a bounded number of layers  $\rightarrow V^{i+1} = V^i$  and  $A^{i+1} = A^i$  (Why?)
- directed edges:
  - ▶ from  $v^i$  to  $a^{i+1}$  if  $v \in pre(a)$  (precondition edges)
  - from  $a^i$  to  $v^i$  if  $v \in add(a)$  (effect edges)
  - ightharpoonup from  $v^i$  to  $v^{i+1}$  (no-op edges)
  - ▶ from  $v^n$  to g if  $v \in G$  (goal edges)

## Generic Relaxed Planning Graph Heuristic

```
Heuristic Values from Relaxed Planning Graph function generic-rpg-heuristic(\langle V,I,G,A\rangle,s): \Pi^+:=\langle V,s,G,A^+\rangle for k\in\{0,1,2,\ldots\}: rpg:=RPG_k(\Pi^+) \qquad \text{[relaxed planning graph to layer $k$]} if rpg contains a goal node: Annotate nodes of rpg. \text{if termination criterion is true:} \text{return heuristic value from annotations} else if graph has stabilized: \text{return } \infty
```

- → general template for RPG heuristics
- via to obtain concrete heuristic: instantiate highlighted elements

F4. Automated Planning: Delete Relaxation Heuristics

Relaxed Planning Graphs

## Concrete Examples for Generic RPG Heuristic

Many planning heuristics fit this general template.

In this course:

- maximum heuristic h<sup>max</sup> (Bonet & Geffner, 1999)
- ▶ additive heuristic h<sup>add</sup> (Bonet, Loerincs & Geffner, 1997)
- Keyder & Geffner's (2008) variant of the FF heuristic h<sup>FF</sup> (Hoffmann & Nebel, 2001)

German: Maximum-Heuristik, additive Heuristik, FF-Heuristik

#### remark:

► The most efficient implementations of these heuristics do not use explicit planning graphs, but rather alternative (equivalent) definitions.

Maximum and Additive Heuristics

# F4.2 Maximum and Additive Heuristics

F4. Automated Planning: Delete Relaxation Heuristics

Maximum and Additive Heuristics

#### Maximum and Additive Heuristics

- $\blacktriangleright$   $h^{\text{max}}$  and  $h^{\text{add}}$  are the simplest RPG heuristics.
- Vertex annotations are numerical values.
- The vertex values estimate the costs
  - to make a given variable true
  - to reach and apply a given action
  - to reach the goal

Maximum and Additive Heuristics: Intuition

## Maximum and Additive Heuristics: Filled-in Template

 $h^{\text{max}}$  and  $h^{\text{add}}$ 

computation of annotations:

costs of variable vertices:
 0 in layer 0;
 otherwise minimum of the costs of predecessor vertices

costs of action and goal vertices: maximum (h<sup>max</sup>) or sum (h<sup>add</sup>) of predecessor vertex costs; for action vertices a<sup>i</sup>, also add cost(a)

termination criterion:

**stability**: terminate if  $V^i = V^{i-1}$  and costs of all vertices in  $V^i$  equal corresponding vertex costs in  $V^{i-1}$ 

heuristic value:

value of goal vertex

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

May 5, 2025

13 /

#### intuition:

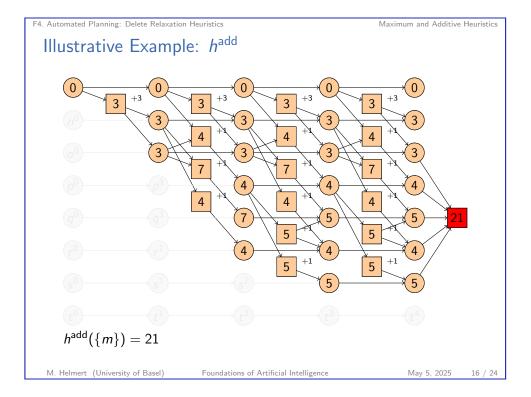

- variable vertices:
  - choose cheapest way of reaching the variable
- ► action/goal vertices:
  - h<sup>max</sup> is optimistic: assumption: when reaching the most expensive precondition variable, we can reach the other precondition variables in parallel (hence maximization of costs)
  - h<sup>add</sup> is pessimistic: assumption: all precondition variables must be reached completely independently of each other (hence summation of costs)

## $h^{\text{max}}$ and $h^{\text{add}}$ : Remarks

comparison of  $h^{\text{max}}$  and  $h^{\text{add}}$ :

- both are safe and goal-aware
- $ightharpoonup h^{\text{max}}$  is admissible and consistent;  $h^{\text{add}}$  is neither.
- $\rightarrow$   $h^{\text{add}}$  not suited for optimal planning
- ▶ However,  $h^{\text{add}}$  is usually much more informative than  $h^{\text{max}}$ . Greedy best-first search with  $h^{\text{add}}$  is a decent algorithm.
- $\triangleright$  Apart from not being admissible,  $h^{add}$  often vastly overestimates the actual costs because positive synergies between subgoals are not recognized.

→ FF heuristic

## F4.3 FF Heuristic

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

May 5, 2025

F4. Automated Planning: Delete Relaxation Heuristics

## FF Heuristic

#### The FF Heuristic

identical to  $h^{\text{add}}$ , but additional steps at the end:

- ► Mark goal vertex.
- ► Apply the following marking rules until nothing more to do:
  - marked action or goal vertex?
    - → mark all predecessors
  - ightharpoonup marked variable vertex  $v^i$  in layer i > 1?  $\rightsquigarrow$  mark one predecessor with minimal  $h^{\text{add}}$  value (tie-breaking: prefer variable vertices; otherwise arbitrary)

#### heuristic value:

- ▶ The actions corresponding to the marked action vertices build a relaxed plan.
- ► The cost of this plan is the heuristic value.

F4. Automated Planning: Delete Relaxation Heuristics FF Heuristic Illustrative Example:  $h^{FF}$  $h^{\mathsf{FF}}(\{m\}) = 3 + 1 + 1 + 1 + 1 = 7$ M. Helmert (University of Basel) Foundations of Artificial Intelligence May 5, 2025

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

May 5, 2025

F4. Automated Planning: Delete Relaxation Heuristics

FF Heuristic

FF Heuristic: Remarks

► Like *h*<sup>add</sup>, *h*<sup>FF</sup> is safe and goal-aware, but neither admissible nor consistent.

ightharpoonup approximation of  $h^+$  which is always at least as good as  $h^{add}$ 

usually significantly better

▶ can be computed in almost linear time  $(O(n \log n))$  in the size of the description of the planning task

 computation of heuristic value depends on tie-breaking of marking rules (h<sup>FF</sup> not well-defined)

▶ one of the most successful planning heuristics

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

May 5, 2025

21 / 24

F4. Automated Planning: Delete Relaxation Heuristics

FF Heuristic

## Comparison of Relaxation Heuristics

#### Relationships of Relaxation Heuristics

Let s be a state in the STRIPS planning task  $\langle V, I, G, A \rangle$ .

#### Then

- $h^{\max}(s) \leq h^+(s) \leq h^*(s)$
- $h^{\text{max}}(s) \leq h^+(s) \leq h^{\text{FF}}(s) \leq h^{\text{add}}(s)$
- $\blacktriangleright$   $h^*$  and  $h^{\mathsf{FF}}$  are incomparable
- $\blacktriangleright$   $h^*$  and  $h^{\text{add}}$  are incomparable

#### further remarks:

- ► For non-admissible heuristics, it is generally neither good nor bad to compute higher values than another heuristic.
- ▶ For relaxation heuristics, the objective is to approximate  $h^+$  as closely as possible.

M. Helmert (University of Basel)

Foundations of Artificial Intelligence

May 5, 2025

F4. Automated Planning: Delete Relaxation Heuristics

Summar

# F4.4 Summary

F4. Automated Planning: Delete Relaxation Heuristics

Summa

## Summary

- ► Many delete relaxation heuristics can be viewed as computations on relaxed planning graphs (RPGs).
- ightharpoonup examples:  $h^{\text{max}}$ ,  $h^{\text{add}}$ ,  $h^{\text{FF}}$
- $ightharpoonup h^{\text{max}}$  and  $h^{\text{add}}$  propagate numeric values in the RPGs
  - ▶ difference:  $h^{\text{max}}$  computes the maximum of predecessor costs for action and goal vertices;  $h^{\text{add}}$  computes the sum
- ► h<sup>FF</sup> marks vertices and sums the costs of marked action vertices.
- generally:  $h^{\max}(s) \le h^+(s) \le h^{\mathsf{FF}}(s) \le h^{\mathsf{add}}(s)$
