A8.6 Summary

## Content of this Course

# A8.1 Motivation

## How Difficult is Planning?

- ▶ Using **state-space search** (e.g., using Dijkstra's algorithm on the transition system), planning can be solved in **polynomial time** in the **number of states**.
- ▶ However, the number of states is **exponential** in the number of **state variables**, and hence in general exponential in the size of the input to the planning algorithm.
- ↪ Do non-exponential planning algorithms exist?
- ↪ What is the precise **computational complexity** of planning?

## Why Computational Complexity?

- ▶ **understand** the problem
- ▶ know what is **not** possible
- ▶ find interesting **subproblems** that are easier to solve
- ▶ distinguish **essential features** from **syntactic sugar**
  - ▶ Is STRIPS planning easier than general planning?
  - ▶ Is planning for FDR tasks harder than for propositional tasks?

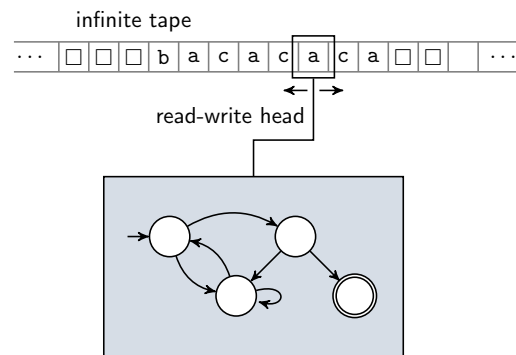

## A8.2 Background: Complexity Theory

## Reminder: Complexity Theory

### Need to Catch Up?

- ▶ We assume knowledge of complexity theory:
  - ▶ languages and decision problems
  - ▶ Turing machines: NTMs and DTMs; polynomial equivalence with other models of computation
  - ▶ complexity classes: P, NP, PSPACE
  - ▶ polynomial reductions
- ▶ If you are not familiar with these topics, we recommend **Chapters C7, E1–E3, E6** of the **Theory of Computer Science** course at <https://dmi.unibas.ch/en/academics/computer-science/courses-in-spring-semester-2020/lecture-theory-of-computer-science/>

## Turing Machines: Conceptually

## Turing Machines

### Definition (Nondeterministic Turing Machine)

A **nondeterministic Turing machine (NTM)** is a 6-tuple  $\langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  with the following components:

- ▶ **input alphabet**  $\Sigma$  and **blank symbol**  $\square \notin \Sigma$ 
  - ▶ alphabets always nonempty and finite
  - ▶ **tape alphabet**  $\Sigma_{\square} = \Sigma \cup \{\square\}$
- ▶ finite set  $Q$  of **internal states** with **initial state**  $q_0 \in Q$  and **accepting state**  $q_Y \in Q$ 
  - ▶ **nonterminal states**  $Q' := Q \setminus \{q_Y\}$
- ▶ **transition relation**  $\delta : (Q' \times \Sigma_{\square}) \rightarrow 2^{Q \times \Sigma_{\square} \times \{-1, +1\}}$

### Deterministic Turing machine (DTM):

$$|\delta(q, s)| = 1 \text{ for all } \langle q, s \rangle \in Q' \times \Sigma_{\square}$$

## Turing Machines: Accepted Words

- ▶ **Initial configuration**
  - ▶ state  $q_0$
  - ▶ input word on tape, all other tape cells contain  $\square$
  - ▶ head on first symbol of input word
- ▶ **Step**
  - ▶ If in state  $q$ , reading symbol  $s$ , and  $\langle q', s', d \rangle \in \delta(q, s)$  then the NTM **can** transition to state  $q'$ , replacing  $s$  with  $s'$  and moving the head one cell to the left/right ( $d = -1/+1$ ).
- ▶ Input word ( $\in \Sigma^*$ ) is **accepted** if **some** sequence of transitions brings the NTM from the initial configuration into state  $q_Y$ .

## Acceptance in Time and Space

### Definition (Acceptance of a Language in Time/Space)

Let  $f : \mathbb{N}_0 \rightarrow \mathbb{N}_0$ .

A NTM **accepts** language  $L \subseteq \Sigma^*$  **in time**  $f$  if it accepts each  $w \in L$  within  $f(|w|)$  steps and does not accept any  $w \notin L$  (in any time).

It **accepts** language  $L \subseteq \Sigma^*$  **in space**  $f$  if it accepts each  $w \in L$  using at most  $f(|w|)$  tape cells and does not accept any  $w \notin L$ .

## Time and Space Complexity Classes

### Definition (DTIME, NTIME, DSPACE, NSPACE)

Let  $f : \mathbb{N}_0 \rightarrow \mathbb{N}_0$ .

Complexity class **DTIME**( $f$ ) contains all languages accepted in time  $f$  by some DTM.

Complexity class **NTIME**( $f$ ) contains all languages accepted in time  $f$  by some NTM.

Complexity class **DSPACE**( $f$ ) contains all languages accepted in space  $f$  by some DTM.

Complexity class **NSPACE**( $f$ ) contains all languages accepted in space  $f$  by some NTM.

## Polynomial Time and Space Classes

Let  $\mathcal{P}$  be the set of polynomials  $p : \mathbb{N}_0 \rightarrow \mathbb{N}_0$  whose coefficients are natural numbers.

### Definition (P, NP, PSPACE, NPSPACE)

$$\begin{aligned} P &= \bigcup_{p \in \mathcal{P}} \text{DTIME}(p) \\ NP &= \bigcup_{p \in \mathcal{P}} \text{NTIME}(p) \\ PSPACE &= \bigcup_{p \in \mathcal{P}} \text{DSPACE}(p) \\ NPSPACE &= \bigcup_{p \in \mathcal{P}} \text{NSPACE}(p) \end{aligned}$$

## Polynomial Complexity Class Relationships

### Theorem (Complexity Class Hierarchy)

$$P \subseteq NP \subseteq PSPACE = NPSPACE$$

#### Proof.

$P \subseteq NP$  and  $PSPACE \subseteq NPSPACE$  are obvious because deterministic Turing machines are a special case of nondeterministic ones.

$NP \subseteq NPSPACE$  holds because a Turing machine can only visit polynomially many tape cells within polynomial time.

$PSPACE = NPSPACE$  is a special case of a classical result known as Savitch's theorem (Savitch 1970).  $\square$

## A8.3 (Bounded-Cost) Plan Existence

## Decision Problems for Planning

### Definition (Plan Existence)

**Plan existence (PLANEX)** is the following decision problem:

**GIVEN:** planning task  $\Pi$

**QUESTION:** Is there a plan for  $\Pi$ ?

$\rightsquigarrow$  decision problem analogue of **satisficing planning**

### Definition (Bounded-Cost Plan Existence)

**Bounded-cost plan existence (BCPLANEX)**

is the following decision problem:

**GIVEN:** planning task  $\Pi$ , cost bound  $K \in \mathbb{N}_0$

**QUESTION:** Is there a plan for  $\Pi$  with cost at most  $K$ ?

$\rightsquigarrow$  decision problem analogue of **optimal planning**

## Plan Existence vs. Bounded-Cost Plan Existence

### Theorem (Reduction from PLANEX to BCPLANEX)

$\text{PLANEX} \leq_p \text{BCPLANEX}$

### Proof.

Consider a planning task  $\Pi$  with state variables  $V$ .

Let  $c_{\max}$  be the maximal cost of all operators of  $\Pi$ .

Compute the number of states of  $\Pi$  as  $N = \prod_{v \in V} |\text{dom}(v)|$ .

(For propositional state variable, define  $\text{dom}(v) = \{T, F\}$ .)

$\Pi$  is solvable iff there is solution with cost at most  $c_{\max} \cdot (N - 1)$  because a solution need not visit any state twice.

$\rightsquigarrow$  map instance  $\Pi$  of PLANEX to instance  $\langle \Pi, c_{\max} \cdot (N - 1) \rangle$  of BCPLANEX

$\rightsquigarrow$  polynomial reduction □

## A8.4 PSPACE-Completeness of Planning

## Membership in PSPACE

### Theorem

$\text{BCPLANEX} \in \text{PSPACE}$

### Proof.

Show  $\text{BCPLANEX} \in \text{NPSPACE}$  and use Savitch's theorem.

**Nondeterministic algorithm:**

```

def plan( $\langle V, I, O, \gamma \rangle, K$ ):
     $s := I$ 
     $k := K$ 
    loop forever:
        if  $s \models \gamma$ : accept
        guess  $o \in O$ 
        if  $o$  is not applicable in  $s$ : fail
        if  $\text{cost}(o) > k$ : fail
         $s := s[o]$ 
         $k := k - \text{cost}(o)$ 
  
```

□

## PSPACE-Hardness

### Idea: generic reduction

- ▶ For an arbitrary fixed DTM  $M$  with space bound polynomial  $p$  and input  $w$ , generate propositional planning task which is solvable iff  $M$  accepts  $w$  in space  $p(|w|)$ .
- ▶ Without loss of generality, we assume  $p(n) \geq n$  for all  $n$ .

## Reduction: State Variables

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be the fixed DTM, and let  $p$  be its space-bound polynomial.

Given input  $w_1 \dots w_n$ , define relevant tape positions  $X := \{-p(n), \dots, p(n)\}$

### State Variables

- ▶  $\text{state}_q$  for all  $q \in Q$
  - ▶  $\text{head}_i$  for all  $i \in X \cup \{-p(n) - 1, p(n) + 1\}$
  - ▶  $\text{content}_{i,a}$  for all  $i \in X, a \in \Sigma_{\square}$
- $\rightsquigarrow$  allows encoding a Turing machine configuration

## Reduction: Initial State

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be the fixed DTM, and let  $p$  be its space-bound polynomial.

Given input  $w_1 \dots w_n$ , define relevant tape positions  $X := \{-p(n), \dots, p(n)\}$

### Initial State

Initially true:

- ▶  $\text{state}_{q_0}$
- ▶  $\text{head}_1$
- ▶  $\text{content}_{i,w_i}$  for all  $i \in \{1, \dots, n\}$
- ▶  $\text{content}_{i,\square}$  for all  $i \in X \setminus \{1, \dots, n\}$

Initially false:

- ▶ all others

## Reduction: Operators

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be the fixed DTM, and let  $p$  be its space-bound polynomial.

Given input  $w_1 \dots w_n$ , define relevant tape positions  $X := \{-p(n), \dots, p(n)\}$

### Operators

One operator for each transition rule  $\delta(q, a) = \langle q', a', d \rangle$  and each cell position  $i \in X$ :

- ▶ precondition:  $\text{state}_q \wedge \text{head}_i \wedge \text{content}_{i,a}$
- ▶ effect:  $\neg \text{state}_q \wedge \neg \text{head}_i \wedge \neg \text{content}_{i,a} \wedge \text{state}_{q'} \wedge \text{head}_{i+d} \wedge \text{content}_{i,a'}$

Note that add-after-delete semantics are important here!

## Reduction: Goal

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be the fixed DTM,  
and let  $p$  be its space-bound polynomial.

Given input  $w_1 \dots w_n$ , define **relevant tape positions**  
 $X := \{-p(n), \dots, p(n)\}$

Goal  
state $_{q_Y}$

## PSPACE-Completeness of STRIPS Plan Existence

**Theorem (PSPACE-Completeness; Bylander, 1994)**

$\text{PLANEX}$  and  $\text{BCPLANEX}$  are PSPACE-complete.  
*This is true even if only STRIPS tasks are allowed.*

**Proof.**

Membership for  $\text{BCPLANEX}$  was already shown.

Hardness for  $\text{PLANEX}$  follows because we just presented a polynomial reduction from an arbitrary problem in PSPACE to  $\text{PLANEX}$ . (Note that the reduction only generates STRIPS tasks, after trivial cleanup to make them conflict-free.)

Membership for  $\text{PLANEX}$  and hardness for  $\text{BCPLANEX}$  follow from the polynomial reduction from  $\text{PLANEX}$  to  $\text{BCPLANEX}$ .  $\square$

## A8.5 More Complexity Results

## More Complexity Results

In addition to the basic complexity result presented in this chapter, there are many special cases, generalizations, variations and related problems studied in the literature:

- ▶ different **planning formalisms**
  - ▶ e.g., nondeterministic effects, partial observability, schematic operators, numerical state variables
- ▶ **syntactic restrictions** of planning tasks
  - ▶ e.g., without preconditions, without conjunctive effects, STRIPS without delete effects
- ▶ **semantic restrictions** of planning task
  - ▶ e.g., restricting variable dependencies (“causal graphs”)
- ▶ **particular planning domains**
  - ▶ e.g., Blocksworld, Logistics, FreeCell

## Complexity Results for Different Planning Formalisms

Some results for different planning formalisms:

- ▶ **nondeterministic effects:**
  - ▶ fully observable: EXP-complete (Littman, 1997)
  - ▶ unobservable: EXPSPACE-complete (Haslum & Jonsson, 1999)
  - ▶ partially observable: 2-EXP-complete (Rintanen, 2004)
- ▶ **schematic operators:**
  - ▶ usually adds one exponential level to PLANEX complexity
  - ▶ e.g., classical case EXPSPACE-complete (Erol et al., 1995)
- ▶ **numerical state variables:**
  - ▶ undecidable in most variations (Helmert, 2002)

## A8.6 Summary

## Summary

- ▶ **PSPACE:** decision problems solvable in **polynomial space**
- ▶  $P \subseteq NP \subseteq PSPACE = NPSPACE$ .
- ▶ **Classical planning** is **PSPACE-complete**.
- ▶ This is true both for **satisficing** and **optimal** planning (rather, the corresponding decision problems).
- ▶ The hardness proof is a polynomial reduction that translates an **arbitrary polynomial-space DTM** into a **STRIPS task**:
  - ▶ DTM configurations are encoded by state variables.
  - ▶ Operators simulate transitions between DTM configurations.
  - ▶ The DTM accepts an input iff there is a plan for the corresponding STRIPS task.
- ▶ This implies that there is **no polynomial algorithm** for classical planning unless  $P = PSPACE$ .
- ▶ It also means that planning is not polynomially reducible to any problem in NP unless  $NP = PSPACE$ .
