# Choice Functions

# Motivation

- In this chapter, we analyze the behaviour of  $h^{\max}$  and  $h^{\text{add}}$  more deeply.
- Our goal is to understand their shortcomings and use this understanding to devise an improved heuristic.
- As a preparation for our analysis, we need some further definitions that concern **choices** in AND/OR graphs.
- The key observation is that if we want to establish the value of a certain node  $n$ , we can to some extent **choose** how we want to achieve the OR nodes that are relevant to achieving  $n$ .

## Preview: Choice Function & Best Achievers

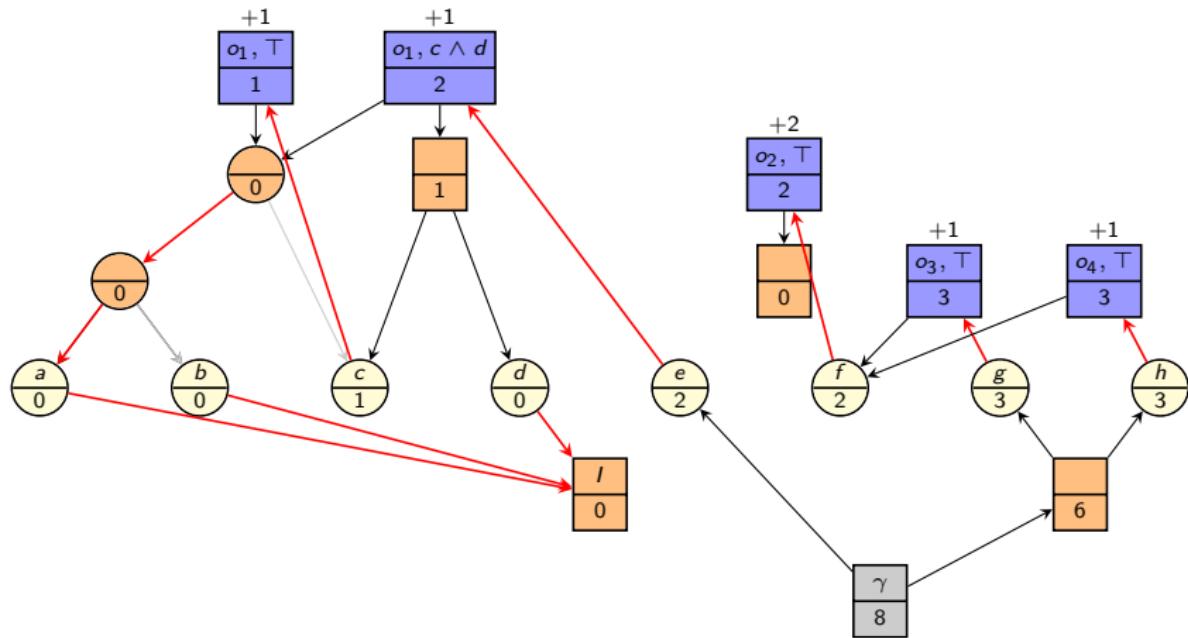

Preserve at most one outgoing arc of each OR node  
but node values may not change.

(precondition of  $o_1$  modified to  $c \vee (a \vee b)$ )

(precondition of  $o_1$  modified to  $c \vee (a \vee b)$ )

# Choice Functions

## Definition (Choice Function)

Let  $G$  be an AND/OR graph with nodes  $N$  and OR nodes  $N_{\text{OR}}$ .

A **choice function** for  $G$  is a function  $f : N' \rightarrow N$  defined on some set  $N' \subseteq N_{\text{OR}}$  such that  $f(n) \in \text{succ}(n)$  for all  $n \in N'$ .

- In words, choice functions select (at most) **one** successor for each OR node of  $G$ .
- Intuitively,  $f(n)$  selects by which disjunct  $n$  is achieved.
- If  $f(n)$  is undefined for a given  $n$ , the intuition is that  $n$  is not achieved.

## Reduced Graphs

Once we have decided how to achieve an OR node, we can remove the other alternatives:

### Definition (Reduced Graph)

Let  $G$  be an AND/OR graph, and let  $f$  be a choice function for  $G$  defined on nodes  $N'$ .

The **reduced graph** for  $f$  is the subgraph of  $G$  where all outgoing arcs of OR nodes are removed except for the chosen arcs  $\langle n, f(n) \rangle$  with  $n \in N'$ .

# Best Achievers

## Choice Functions Induced by $h^{\max}$ and $h^{\text{add}}$

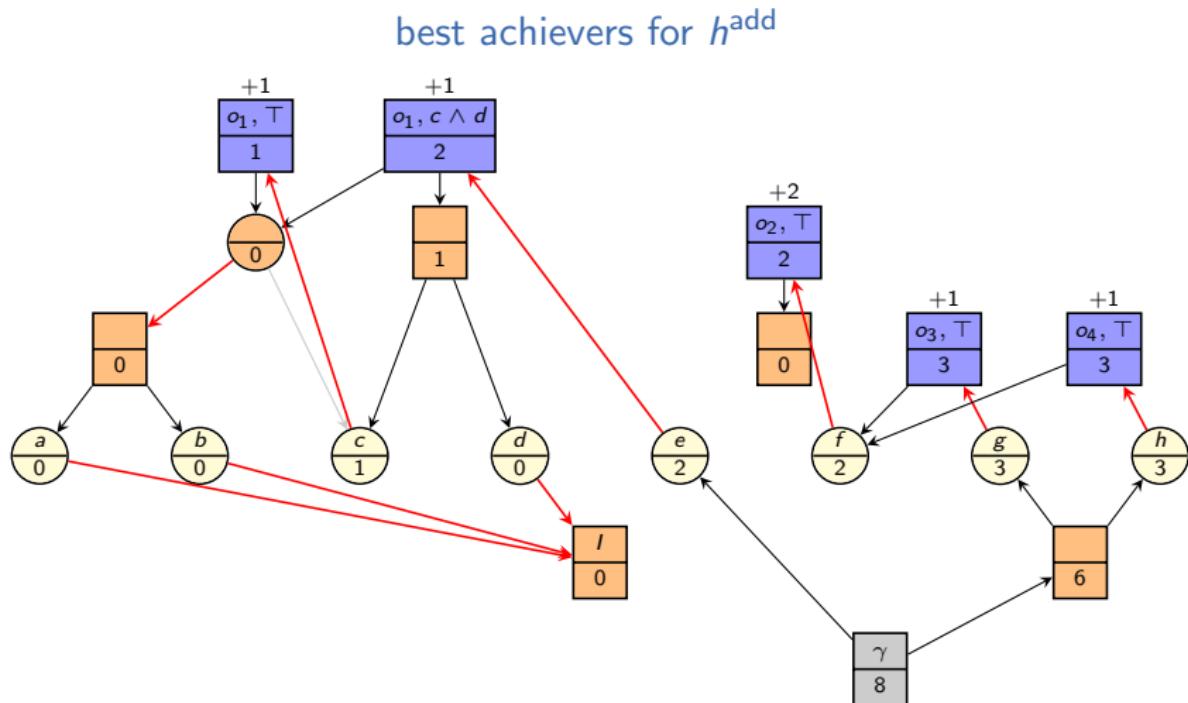

Which choices do  $h^{\max}$  and  $h^{\text{add}}$  make?

- At every OR node  $n$ , we set the cost of  $n$  to the **minimum** of the costs of the successors of  $n$ .
- The motivation for this is to achieve  $n$  via the successor that can be achieved **most cheaply** according to our cost estimates.
- ~~> This corresponds to defining a choice function  $f$  with  $f(n) \in \arg \min_{n' \in N'} n'.cost$  for all reached OR nodes  $n$ , where  $N' \subseteq \text{succ}(n)$  are all successors of  $n$  processed before  $n$ .
- The successors chosen by this cost function are called **best achievers** (according to  $h^{\max}$  or  $h^{\text{add}}$ ).
- Note that the best achiever function  $f$  is in general not well-defined because there can be multiple minimizers. We assume that ties are broken arbitrarily.

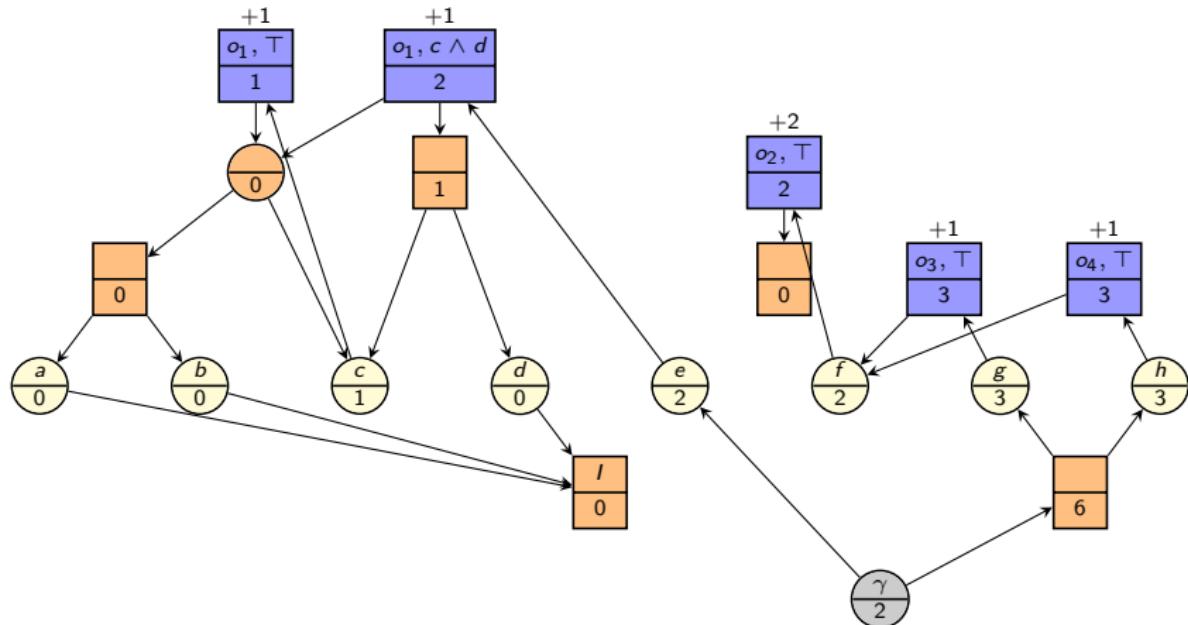

## Example: Best Achievers (1)

best achievers for  $h^{\text{add}}$ 

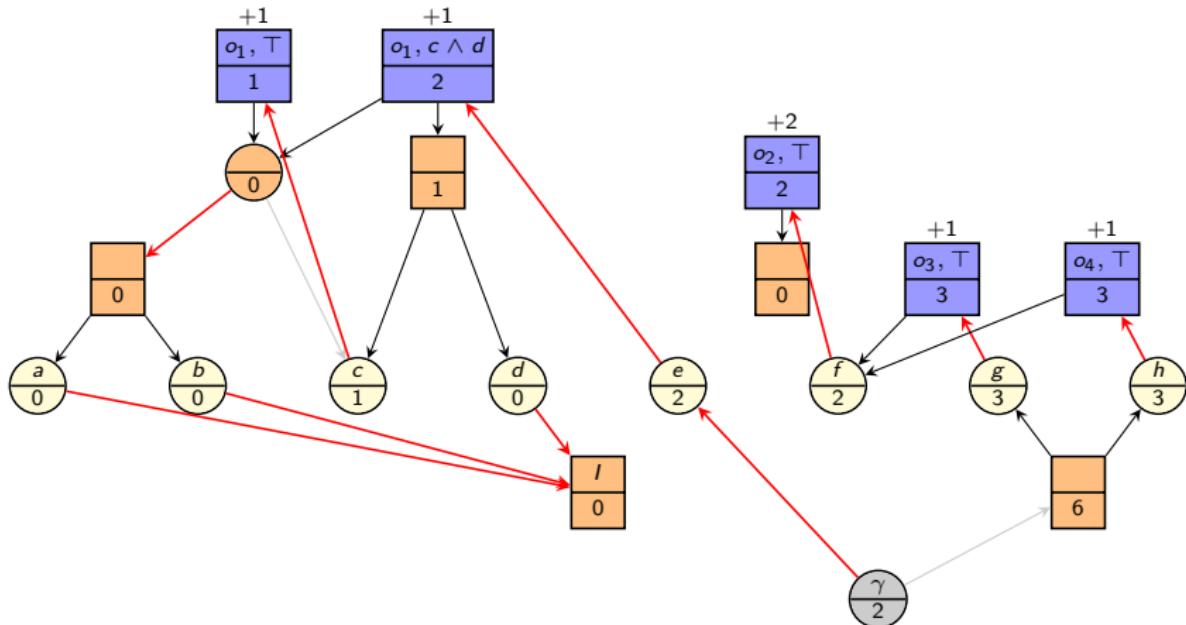

## Example: Best Achievers (1)

## Example: Best Achievers (2)

best achievers for  $h^{\text{add}}$ ; modified goal  $e \vee (g \wedge h)$ 

## Example: Best Achievers (2)

best achievers for  $h^{\text{add}}$ ; modified goal  $e \vee (g \wedge h)$ 

## Best Achiever Graphs

- **Observation:** The  $h^{\max}/h^{\text{add}}$  costs of nodes remain the same if we replace the RTG by the reduced graph for the respective best achiever function.
- The AND/OR graph that is obtained by removing all nodes with infinite cost from this reduced graph is called the **best achiever graph** for  $h^{\max}/h^{\text{add}}$ .
  - We write  $G^{\max}$  and  $G^{\text{add}}$  for the best achiever graphs.
- $G^{\max}$  ( $G^{\text{add}}$ ) is always **acyclic**: for all arcs  $\langle n, n' \rangle$  it contains,  $n$  is processed by  $h^{\max}$  (by  $h^{\text{add}}$ ) after  $n'$ .

# Paths in Best Achiever Graphs

Let  $n$  be a node of the best achiever graph.

Let  $N_{\text{eff}}$  be the set of effect nodes of the best achiever graph.

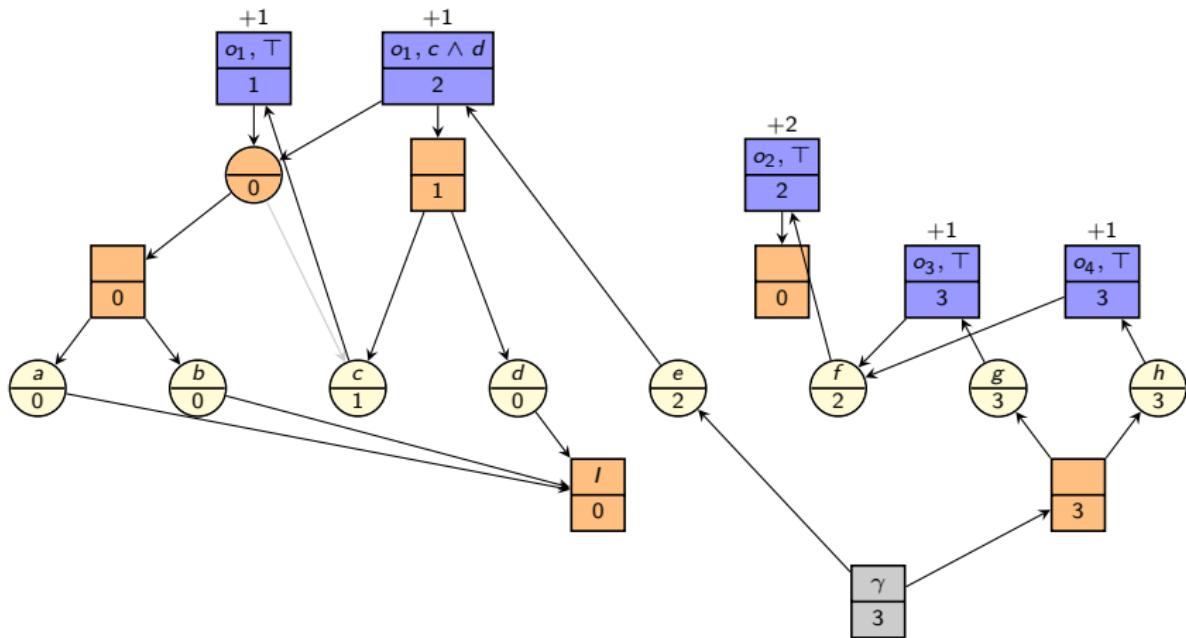

The **cost** of an **effect node** is the cost of the associated operator.

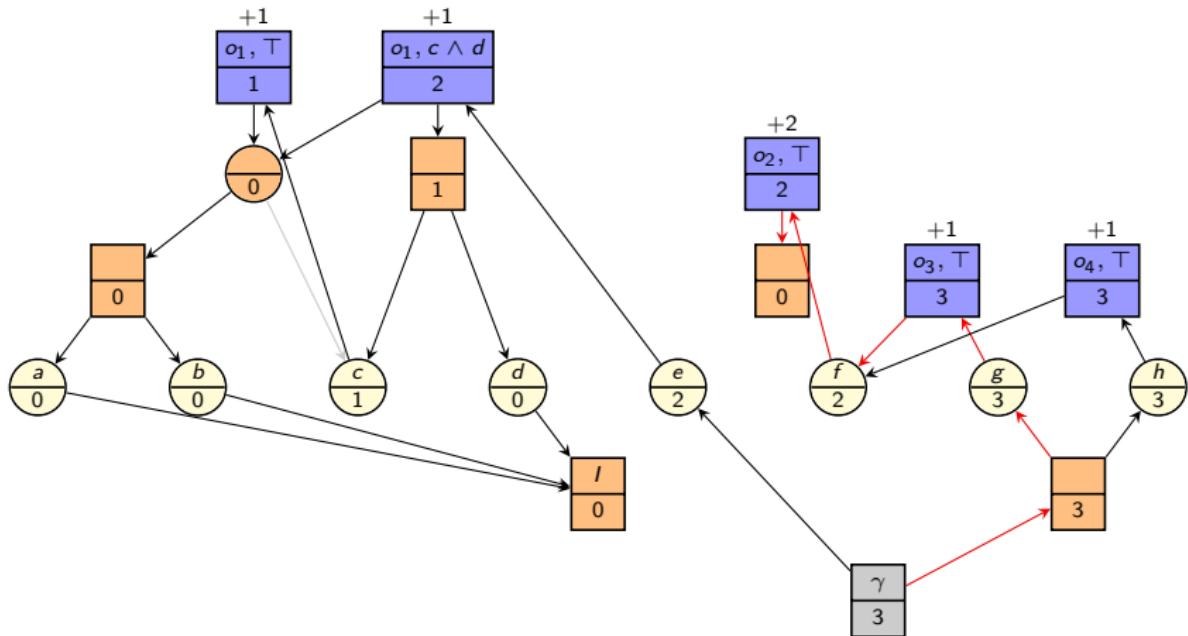

The **cost** of a **path** in the best achiever graph is the sum of costs of all **effect nodes** on the path.

The following properties can be shown by induction:

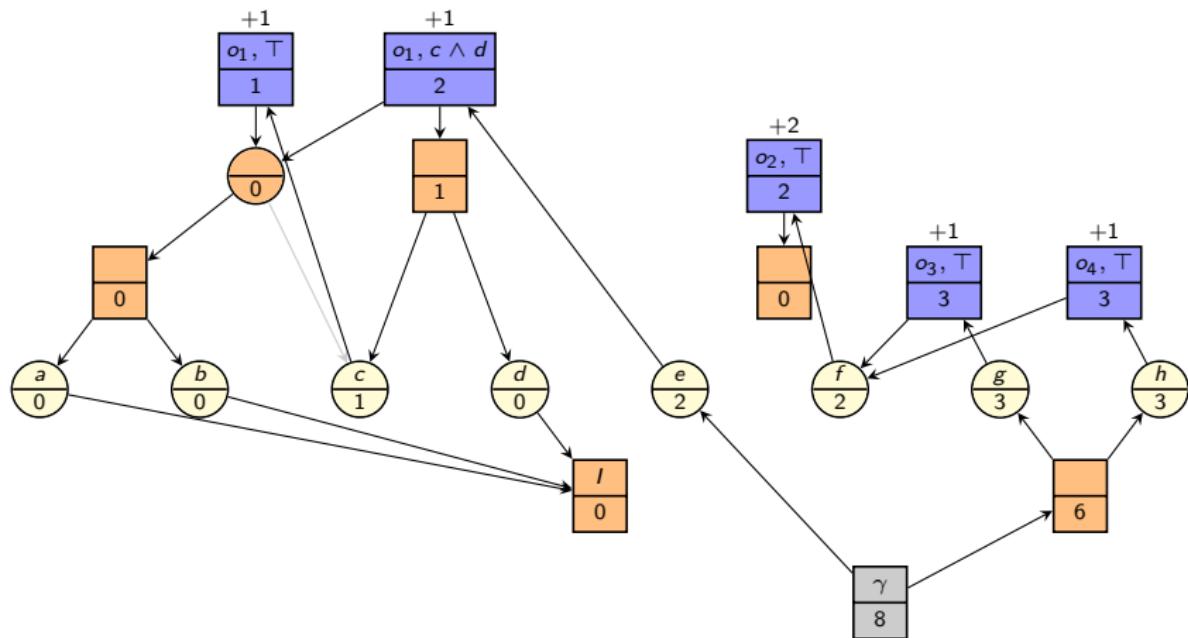

- $h^{\max}(n)$  is the **maximum cost** of all paths originating from  $n$  in  $G^{\max}$ . A path achieving this maximum is called a **critical path**.
- $h^{\text{add}}(n)$  is the **sum**, over all effect nodes  $n'$ , of the cost of  $n'$  multiplied by the **number of paths** from  $n$  to  $n'$  in  $G^{\text{add}}$ .

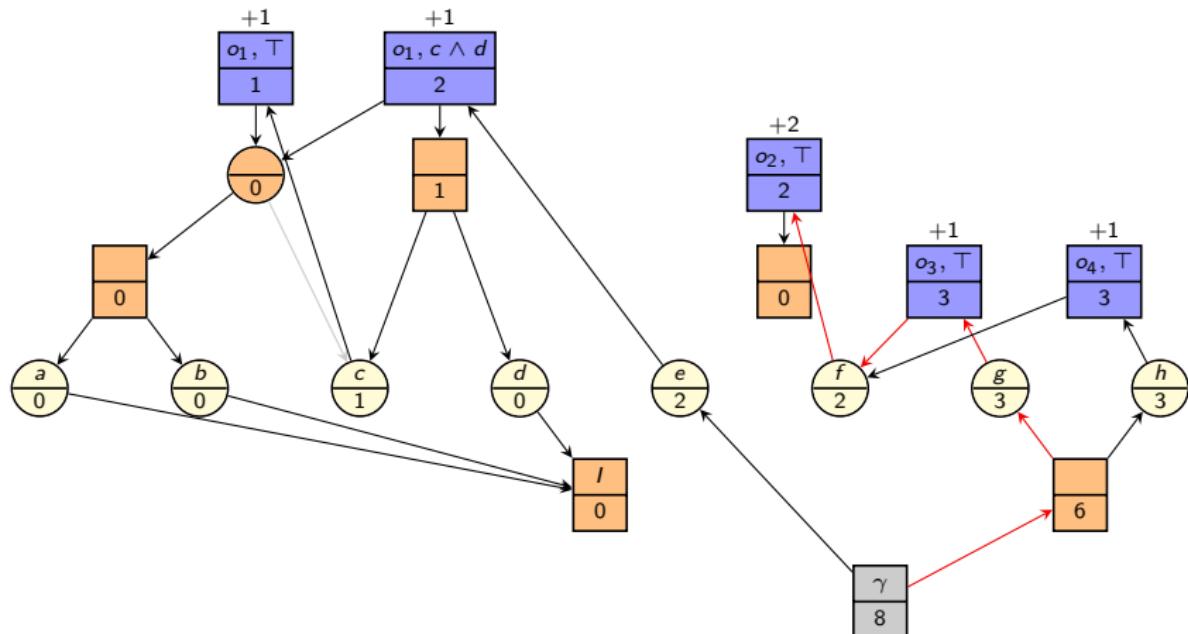

In particular, these properties hold for the goal node  $n_\gamma$  if it is reachable.

Example: Undercounting in  $h^{\max}$  $G^{\max}$ : undercounting in  $h^{\max}$ 

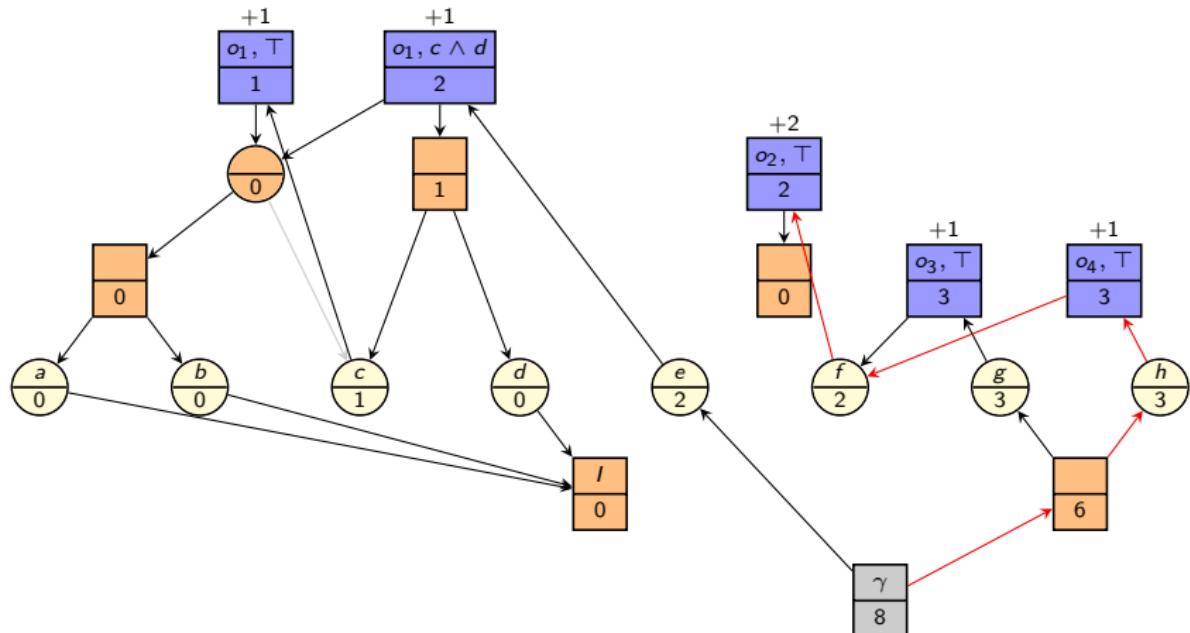

Example: Undercounting in  $h^{\max}$  $G^{\max}$ : undercounting in  $h^{\max}$ 

~ $\rightsquigarrow o_1$  and  $o_4$  not counted because they are off the critical path

Example: Overcounting in  $h^{\text{add}}$  $G^{\text{add}}$ : overcounting in  $h^{\text{add}}$ 

Example: Overcounting in  $h^{\text{add}}$  $G^{\text{add}}$ : overcounting in  $h^{\text{add}}$ 

~~  $o_2$  counted twice because there are two paths to  $n_{o_2}^T$

Example: Overcounting in  $h^{\text{add}}$  $G^{\text{add}}$ : overcounting in  $h^{\text{add}}$ 

$\rightsquigarrow o_2$  counted twice because there are two paths to  $n_{o_2}^T$

Summary  
ooo

# The FF Heuristic

## Inaccuracies in $h^{\max}$ and $h^{\text{add}}$

- $h^{\max}$  is often inaccurate because it **undercounts**:  
the heuristic estimate only reflects the cost of a critical path,  
which is often only a small fraction of the overall plan.
- $h^{\text{add}}$  is often inaccurate because it **overcounts**:  
if the same subproblem is reached in many ways, it will be  
counted many times although it only needs to be solved once.

# The FF Heuristic

Fortunately, with the perspective of best achiever graphs, there is a simple solution: count all effect nodes that  $h^{\text{add}}$  would count, but only count each of them once.

## Definition (FF Heuristic)

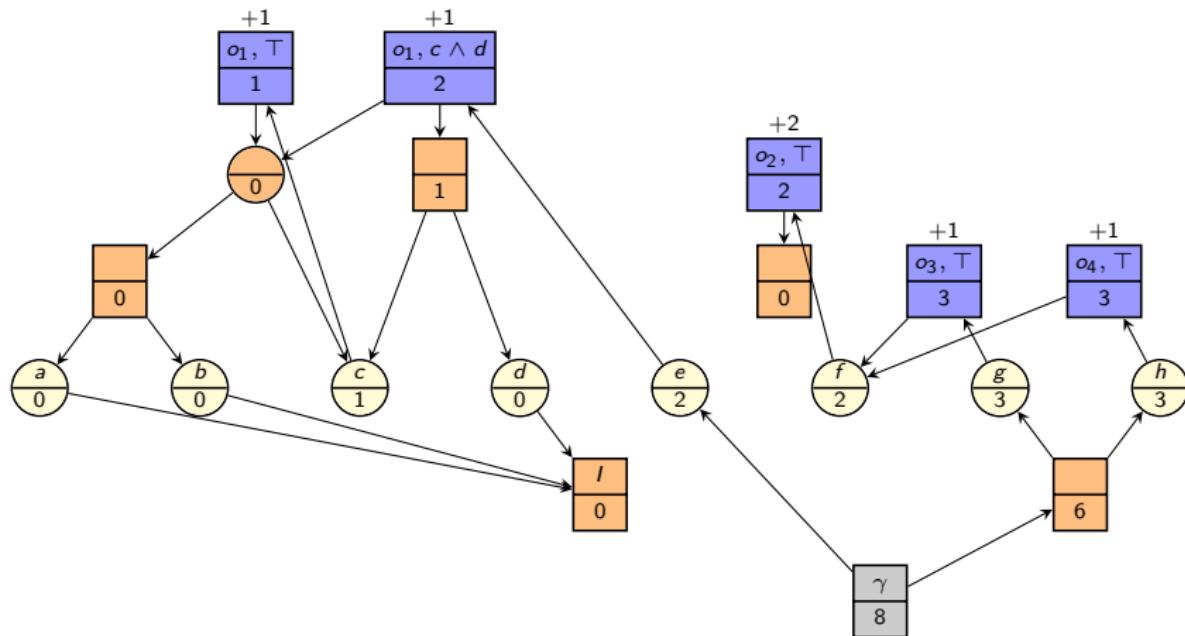

Let  $\Pi = \langle V, I, O, \gamma \rangle$  be a propositional planning task in positive normal form. The **FF heuristic** for a state  $s$  of  $\Pi$ , written  $h^{\text{FF}}(s)$ , is computed as follows:

- Construct the RTG for the task  $\langle V, s, O^+, \gamma \rangle$ .
- Construct the best achiever graph  $G^{\text{add}}$ .
- Compute the set of effect nodes  $\{n_{o_1}^{\chi_1}, \dots, n_{o_k}^{\chi_k}\}$  reachable from  $n_\gamma$  in  $G^{\text{add}}$ .
- Return  $h^{\text{FF}}(s) = \sum_{i=1}^k \text{cost}(o_i)$ .

**Note:**  $h^{\text{FF}}$  is **not** well-defined; different tie-breaking policies for best achievers can lead to different heuristic values

## Example: FF Heuristic (1)

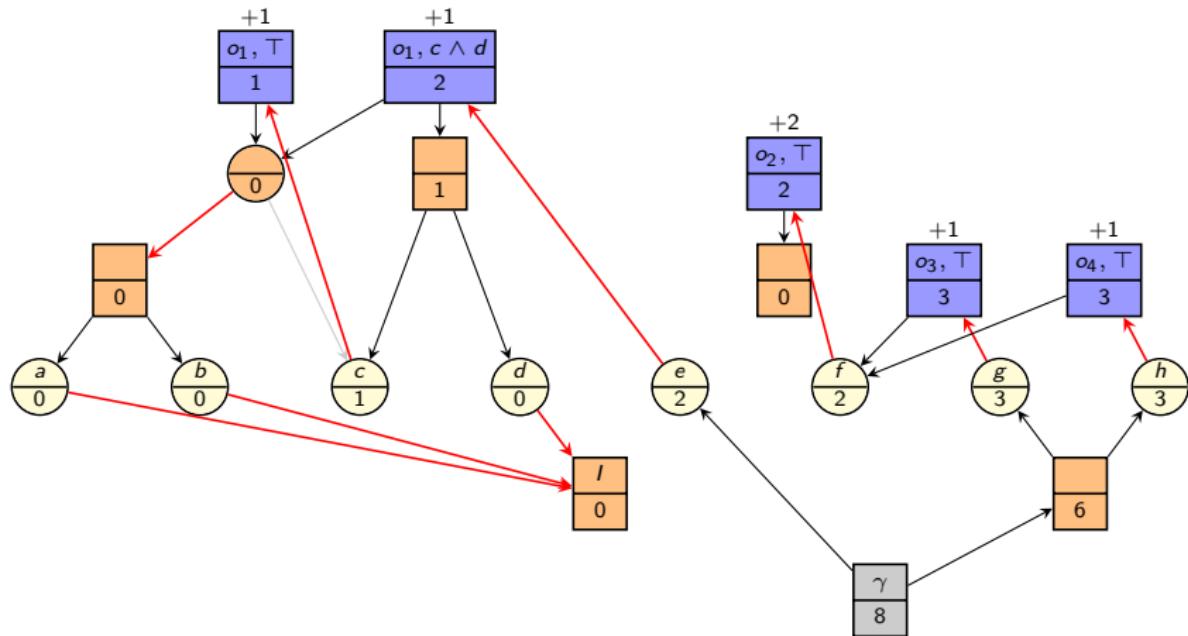

## FF heuristic computation

## Construct RTG.

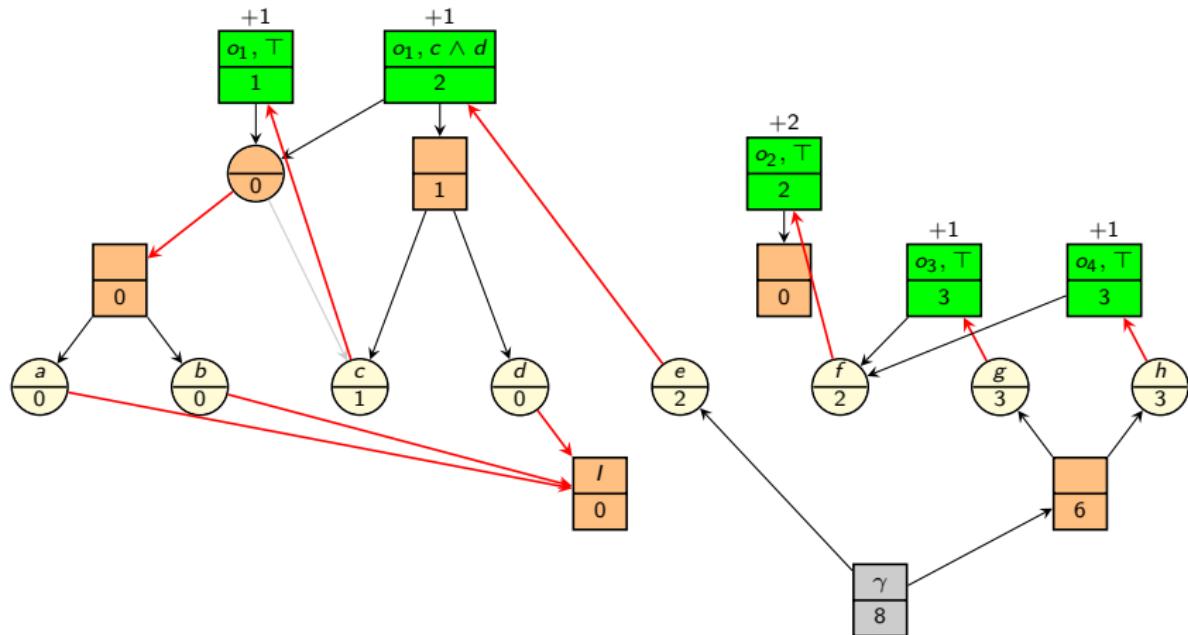

## Example: FF Heuristic (1)

## FF heuristic computation

Construct best achiever graph  $G^{\text{add}}$ .

## Example: FF Heuristic (1)

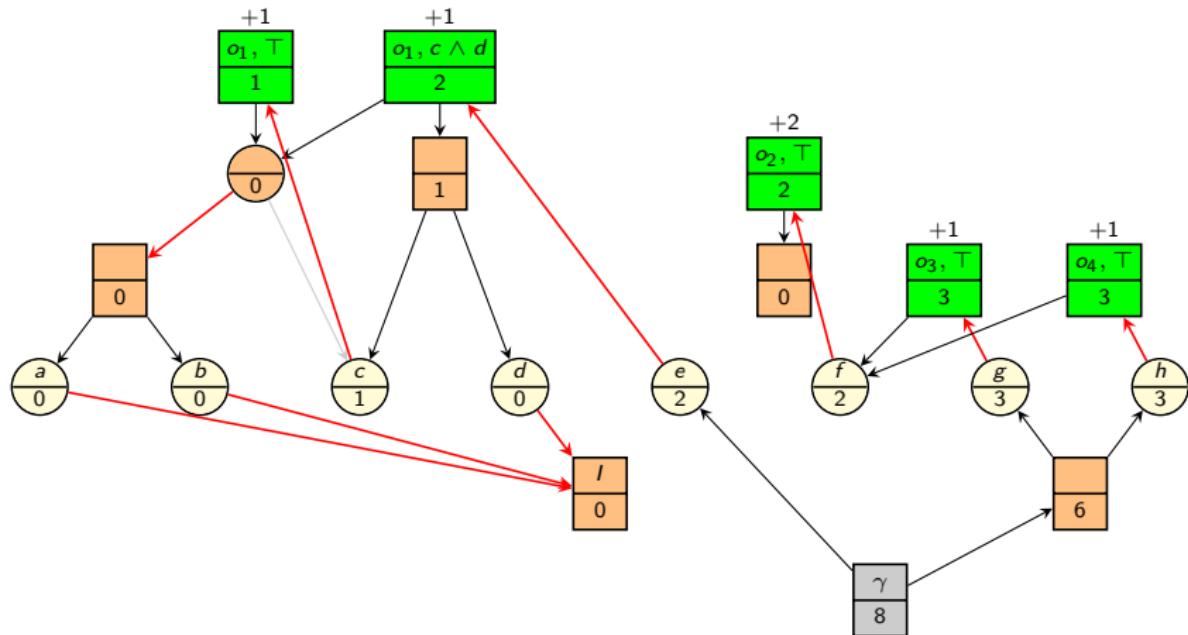

## FF heuristic computation

Compute effect nodes reachable from goal node.

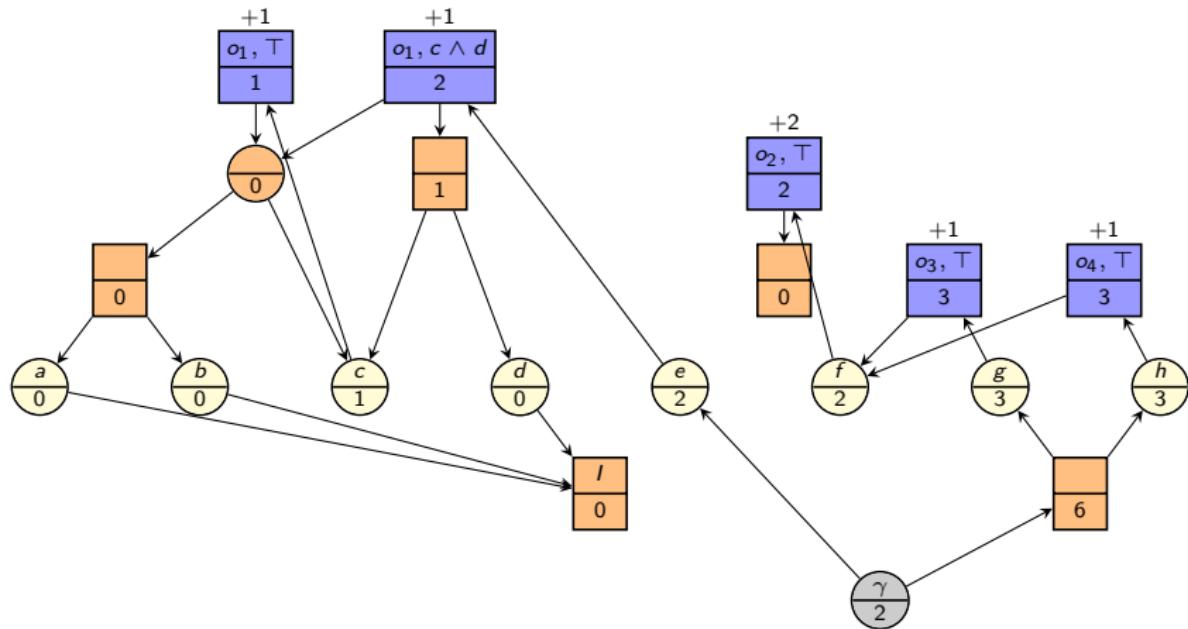

## Example: FF Heuristic (1)

## FF heuristic computation

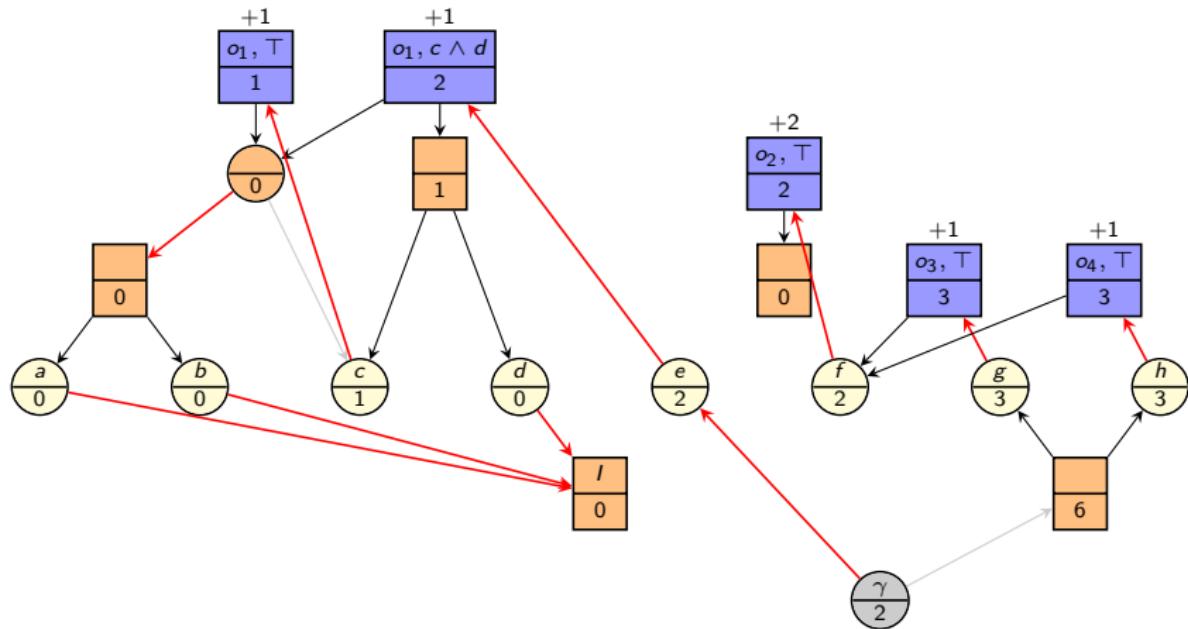

$$h^{\text{FF}}(s) = 1 + 1 + 2 + 1 + 1 = 6$$

## Example: FF Heuristic (2)

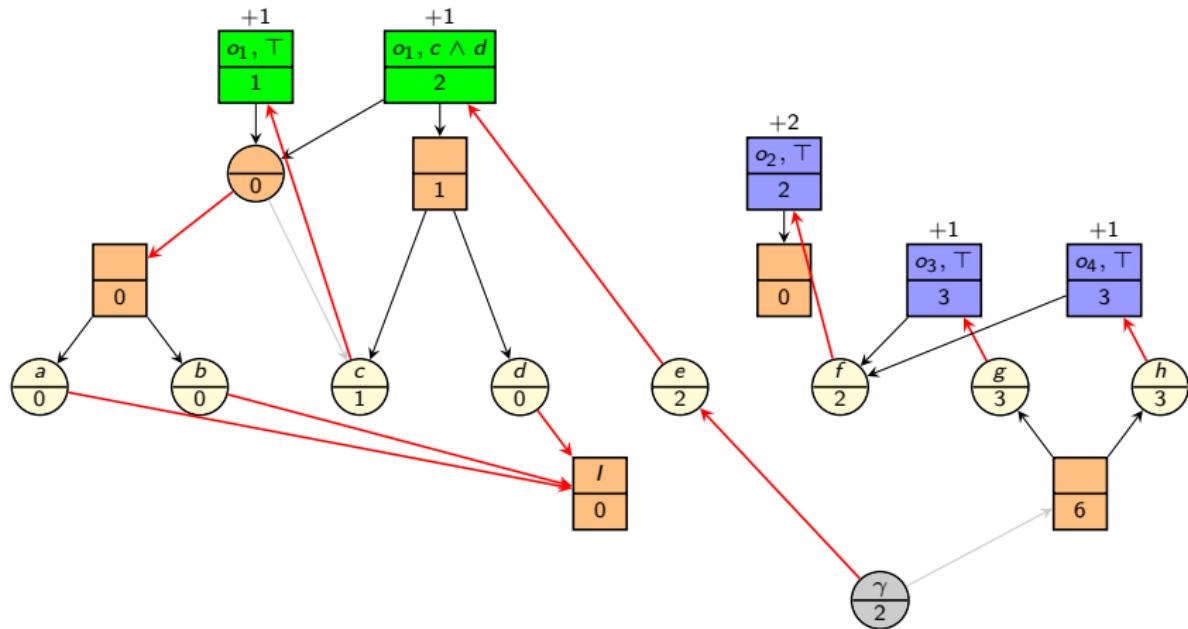

FF heuristic computation; modified goal  $e \vee (g \wedge h)$ 

Construct RTG.

## Example: FF Heuristic (2)

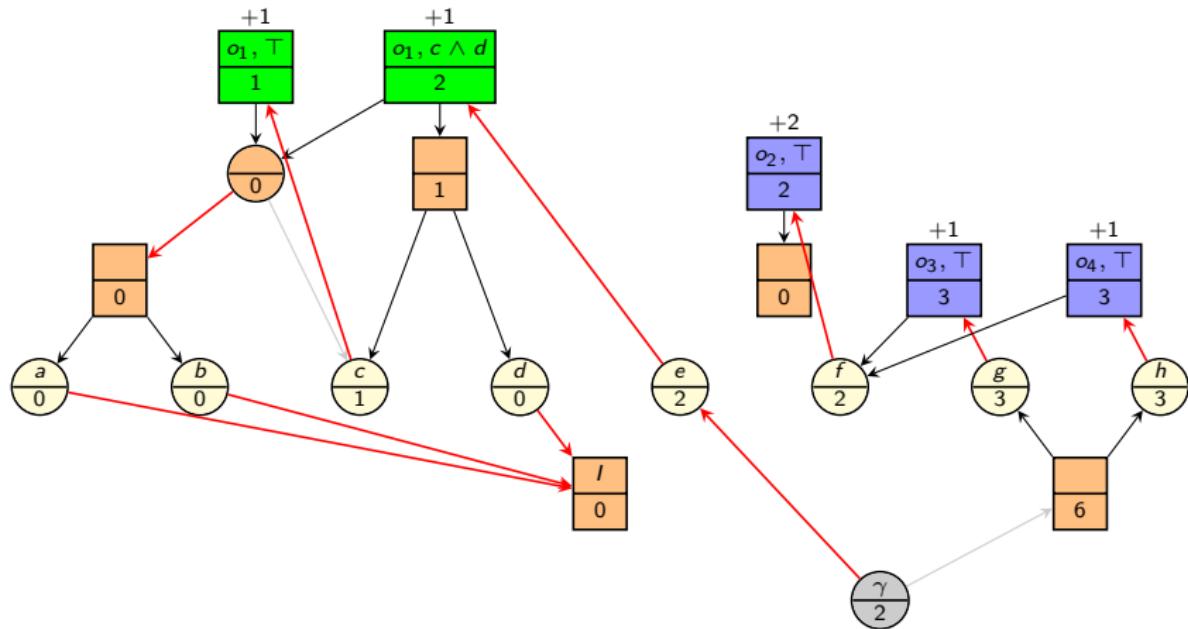

FF heuristic computation; modified goal  $e \vee (g \wedge h)$ Construct best achiever graph  $G^{\text{add}}$ .

## Example: FF Heuristic (2)

FF heuristic computation; modified goal  $e \vee (g \wedge h)$ 

Compute effect nodes reachable from goal node.

## Example: FF Heuristic (2)

FF heuristic computation; modified goal  $e \vee (g \wedge h)$ 

$$h^{\text{FF}}(s) = 1 + 1 = 2$$

# Optimal Delete Relaxation Heuristic

## Definition ( $h^+$ Heuristic)

Let  $\Pi$  be a propositional planning task in positive normal form, and let  $s$  be a state of  $\Pi$ .

The **optimal delete relaxation heuristic** for  $s$ , written  $h^+(s)$ , is defined as the perfect heuristic  $h^*(s)$  of state  $s$  in the delete-relaxed task  $\Pi^+$ .

- **Reminder:** We proved that  $h^+(s)$  is hard to compute. (BCPLANEx is NP-complete for delete-relaxed tasks.)
- The optimal delete relaxation heuristic is often used as a reference point for comparison.

# Relationships between Delete Relaxation Heuristics (1)

## Theorem

Let  $\Pi$  be a propositional planning task in positive normal form, and let  $s$  be a state of  $\Pi$ .

Then:

- ①  $h^{\max}(s) \leq h^+(s) \leq h^{\text{FF}}(s) \leq h^{\text{add}}(s)$
- ②  $h^{\max}(s) = \infty$  iff  $h^+(s) = \infty$  iff  $h^{\text{FF}}(s) = \infty$  iff  $h^{\text{add}}(s) = \infty$
- ③  $h^{\max}$  and  $h^+$  are admissible and consistent.
- ④  $h^{\text{FF}}$  and  $h^{\text{add}}$  are neither admissible nor consistent.
- ⑤ All four heuristics are safe and goal-aware.

## Relationships between Delete Relaxation Heuristics (2)

### Proof Sketch.

for 1:

- To show  $h^{\max}(s) \leq h^+(s)$ , show that critical path costs can be defined for arbitrary relaxed plans and that the critical path cost of a plan is never larger than the cost of the plan.  
Then show that  $h^{\max}(s)$  computes the minimal critical path cost over all delete-relaxed plans.
- To show  $h^+(s) \leq h^{\text{FF}}(s)$ , prove that the operators belonging to the effect nodes counted by  $h^{\text{FF}}$  form a relaxed plan.  
No relaxed plan is cheaper than  $h^+$  by definition of  $h^+$ .
- $h^{\text{FF}}(s) \leq h^{\text{add}}(s)$  is obvious from the description of  $h^{\text{FF}}$ : both heuristics count the same operators,  
but  $h^{\text{add}}$  may count some of them multiple times.

...

## Relationships between Delete Relaxation Heuristics (3)

### Proof Sketch (continued).

for 2: all heuristics are infinite iff the task has no relaxed solution

for 3: follows from  $h^{\max}(s) \leq h^+(s)$

because we already know that  $h^+$  is admissible

for 4: construct a counterexample to admissibility for  $h^{\text{FF}}$

for 5: goal-awareness is easy to show; safety follows from 2.+3. □

Summary  
●○○

# Summary

## Summary

- $h^{\max}$  and  $h^{\text{add}}$  can be used to decide **how** to achieve OR nodes in a relaxed task graph  $\rightsquigarrow$  **best achievers**
- **Best achiever graphs** help identify shortcomings of  $h^{\max}$  and  $h^{\text{add}}$  compared to the perfect delete relaxation heuristic  $h^+$ .
  - $h^{\max}$  **underestimates**  $h^+$  because it only considers the cost of a **critical path** for the relaxed planning task.
  - $h^{\text{add}}$  **overestimates**  $h^+$  because it double-counts operators occurring on **multiple paths** in the best achiever graph.
- The **FF heuristic** repairs this flaw of  $h^{\text{add}}$  and therefore approximates  $h^+$  more closely.
- In general,  $h^{\max}(s) \leq h^+(s) \leq h^{\text{FF}}(s) \leq h^{\text{add}}(s)$ .
- $h^{\max}$  and  $h^+$  are admissible;  $h^{\text{FF}}$  and  $h^{\text{add}}$  are not.

## Literature Pointers

(Some) delete-relaxation heuristics in the planning literature:

- additive heuristic  $h^{\text{add}}$  (Bonet, Loerincs & Geffner, 1997)
- maximum heuristic  $h^{\max}$  (Bonet & Geffner, 1999)
- (original) FF heuristic (Hoffmann & Nebel, 2001)
- cost-sharing heuristic  $h^{\text{cs}}$  (Mirkis & Domshlak, 2007)
- set-additive heuristics  $h^{\text{sa}}$  (Keyder & Geffner, 2008)
- FF/additive heuristic  $h^{\text{FF}}$  (Keyder & Geffner, 2008)
- local Steiner tree heuristic  $h^{\text{lst}}$  (Keyder & Geffner, 2009)
