# Pattern Database Heuristics Informally

### Pattern Databases: Informally

A pattern database heuristic for a planning task is an abstraction heuristic where

some aspects of the task are represented in the abstraction with perfect precision, while

Planning and Optimization

▶ all other aspects of the task are not represented at all.

This is achieved by projecting the task onto the variables that describe the aspects that are represented.

## Example (15-Puzzle)

- Choose a subset T of tiles (the pattern).
- $\blacktriangleright$  Faithfully represent the locations of  ${\cal T}$  in the abstraction.
- Assume that all other tiles and the blank can be anywhere in the abstraction.

Planning and Optimization

7 / 28

# Pattern Database Heuristics

- The most commonly used abstraction heuristics in search and planning are pattern database (PDB) heuristics.
- PDB heuristics were originally introduced for the 15-puzzle (Culberson & Schaeffer, 1996) and for Rubik's cube (Korf, 1997).
- The first use for domain-independent planning is due to Edelkamp (2001).
- Since then, much research has focused on the theoretical properties of pattern databases, how to use pattern databases more effectively, how to find good patterns, etc.
- Pattern databases are a very active research area both in planning and in (domain-specific) heuristic search.
- For many search problems, pattern databases are the most effective admissible heuristics currently known.

Projections and Pattern Database Heuristics

E6. Pattern Databases: Introduction

Projections

Formally, pattern database heuristics are abstraction heuristics induced by a particular class of abstractions called projections.

### Definition (Projection)

Let  $\Pi$  be an FDR planning task with variables V and states S. Let  $P \subseteq V$ , and let S' be the set of states over P. The projection  $\pi_P : S \to S'$  is defined as  $\pi_P(s) := s|_P$ ,

(where  $s|_P(v) := s(v)$  for all  $v \in P$ ).

We call *P* the pattern of the projection  $\pi_P$ .

In other words,  $\pi_P$  maps two states  $s_1$  and  $s_2$  to the same abstract state iff they agree on all variables in P.

Planning and Optimization

8 / 28

Projections and Pattern Database Heuristics

# Pattern Database Heuristics

Abstraction heuristics based on projections are called pattern database (PDB) heuristics.

Definition (Pattern Database Heuristic) The abstraction heuristic induced by  $\pi_P$  is called a pattern database heuristic or PDB heuristic. We write  $h^P$  as a shorthand for  $h^{\pi_P}$ .

Why are they called pattern database heuristics?

- Heuristic values for PDB heuristics are traditionally stored in a 1-dimensional table (array) called a pattern database (PDB). Hence the name "PDB heuristic".
- The word pattern database alludes to endgame databases for 2-player games (in particular chess and checkers).

Implementing PDBs: Precomputation

# Syntactic Projections

Definition (Syntactic Projection)

Let  $\Pi = \langle V, I, O, \gamma \rangle$  be an FDR planning task, and let  $P \subseteq V$  be a subset of its variables. The syntactic projection  $\Pi|_P$  of  $\Pi$  to P is the FDR planning task  $\langle P, I|_P, \{o|_P \mid o \in O\}, \gamma|_P \rangle$ , where

- ▶  $\varphi|_P$  for formula  $\varphi$  is defined as the formula obtained from  $\varphi$  by replacing all atoms (v = d) with  $v \notin P$  by  $\top$ , and
- o|<sub>P</sub> for operator o is defined by replacing all formulas φ occurring in the precondition or effect conditions of o with φ|<sub>P</sub> and all atomic effects (v := d) with v ∉ P with the empty effect ⊤.

Planning and Optimization

Put simply,  $\Pi|_P$  throws away all information not pertaining to variables in P.

E6. Pattern Databases: Introduction

Implementing PDBs: Precomputation

# PDB Computation

Using the equivalence theorem, we can compute pattern databases for SAS<sup>+</sup> tasks  $\Pi$  and patterns *P*:

#### Computing Pattern Databases

**def** compute-PDB( $\Pi$ , P): Compute  $\Pi' := \Pi|_P$ . Compute  $\mathcal{T}' := \mathcal{T}(\Pi')$ . Perform a backward uniform-cost search from the goal states of  $\mathcal{T}'$  to compute all abstract goal distances. PDB := a table containing all goal distances in  $\mathcal{T}'$ **return** PDB

Planning and Optimization

The algorithm runs in polynomial time and space in terms of  $\|\Pi\| + |PDB|$ .

Implementing PDBs: Precomputation

# Going Beyond SAS<sup>+</sup> Tasks

- Most practical implementations of PDB heuristics are limited to SAS<sup>+</sup> tasks (or modest generalizations).
- One way to avoid the issues with general FDR tasks is to convert them to equivalent SAS<sup>+</sup> tasks.
- However, most direct conversions can exponentially increase the task size in the worst case.

Planning and Optimization

 $\rightsquigarrow$  We will only consider SAS<sup>+</sup> tasks in the chapters dealing with pattern databases.

Implementing PDBs: Lookup

21 / 28

November 9, 2022

Lookup Step: Overview

- During search, the PDB is the only piece of information necessary to represent h<sup>P</sup>. (It is not necessary to store the abstract transition system itself at this point.)
- Hence, the space requirements for PDBs during search are linear in the number of abstract states S': there is one table entry for each abstract state.
- During search, h<sup>P</sup>(s) is computed by mapping π<sub>P</sub>(s) to a natural number in the range {0,..., |S'| − 1} using a perfect hash function, then looking up the table entry for this number.

Implementing PDBs: Lookup

# E6. Pattern Databases: Introduction Lookup Step: Algorithm Let P = {v<sub>1</sub>,...,v<sub>k</sub>} be the pattern. We assume that all variable domains are natural numbers counted from 0, i.e., dom(v) = {0, 1, ..., |dom(v)| - 1}. For all i ∈ {1,...,k}, we precompute N<sub>i</sub> := ∏<sub>j=1</sub><sup>i-1</sup> |dom(v<sub>j</sub>)|. Then we can look up heuristic values as follows: Computing Pattern Database Heuristics def PDB-heuristic(s): index := ∑<sub>i=1</sub><sup>k</sup> N<sub>i</sub>s(v<sub>i</sub>) return PDB[index] This is a very fast operation: it can be performed in O(k). For comparison, most relaxation heuristics need time O(||Π||) per state.
