Summary 00

Introduction

Exploiting Additivity

- Additivity allows to add up heuristic estimates admissibly. This gives better heuristic estimates than the maximum.
- For example, the canonical heuristic for PDBs sums up where addition is admissible (by an additivity criterion) and takes the maximum otherwise.
- Cost partitioning provides a more general additivity criterion, based on an adaption of the operator costs.

Introduction

Additivity

When is it impossible to sum up abstraction heuristics admissibly?

- Abstraction heuristics are consistent and goal-aware.
- Sum of goal-aware heuristics is goal aware.
- $\blacksquare \Rightarrow$ Sum of consistent heuristics not necessarily consistent.

Combining Heuristics Admissibly: Example Revisited

Example

Consider an FDR planning task $\langle V, I, \{o_1, o_2, o_3, o_4\}, \gamma \rangle$ with $V = \{v_1, v_2, v_3\}$ with $dom(v_1) = \{A, B\}$ and $dom(v_2) = dom(v_3) = \{A, B, C\}$, $I = \{v_1 \mapsto A, v_2 \mapsto A, v_3 \mapsto A\}$,

$$o_{1} = \langle v_{1} = A, v_{1} := B, 1 \rangle$$

$$o_{2} = \langle v_{2} = A \land v_{3} = A, v_{2} := B \land v_{3} := B, 1 \rangle$$

$$o_{3} = \langle v_{2} = B, v_{2} := C, 1 \rangle$$

$$o_{4} = \langle v_{3} = B, v_{3} := C, 1 \rangle$$

and $\gamma = (v_1 = B) \land (v_2 = C) \land (v_3 = C).$

Combining Heuristics Admissibly: Example

Let $h = h_1 + h_2 + h_3$. Where is consistency violated?

 $h(BCC) = 0 = h^*(BCC)$

Consider solution $\langle o_1, o_2, o_3, o_4 \rangle$

Combining Heuristics Admissibly: Example

 $h(BCB) = 1 = h^*(BCB)$

Consider solution $\langle o_1, o_2, o_3, o_4 \rangle$

Combining Heuristics Admissibly: Example

 $h(BBB) = 2 = h^*(BBB)$

Consider solution $\langle o_1, o_2, o_3, o_4 \rangle$

Saturated Cost Partitioning

Summary 00

Combining Heuristics Admissibly: Example

Let $h = h_1 + h_2 + h_3$. Where is consistency violated?

 $h(BAA) = 4 > 3 = h^*(BAA)$ and $h(BAA) > h(BBB) + cost(o_2)$

 \Rightarrow *h* inconsistent and inadmissible

Consider solution $\langle o_1, o_2, o_3, o_4 \rangle$

Combining Heuristics Admissibly: Example

Let $h = h_1 + h_2 + h_3$. Where is consistency violated?

 $h(AAA) = 5 > h^*(AAA)$

Consider solution $\langle o_1, o_2, o_3, o_4 \rangle$

h is not admissible because $cost(o_2)$ is considered in h_2 and h_3

Is there anything we can do about this?

h is not admissible because $cost(o_2)$ is considered in h_2 and h_3

- Is there anything we can do about this?
- Solution 1:
- We can ignore the cost of o_2 in h_2 or h_3 by setting its cost to 0.

Saturated Cost Partitioning

Summary 00

Combining Heuristics Admissibly: Example

Assume $cost_3(o_2) = 0$ o_2, o_3, o_4 $0_2, 0_3, 0_4$ $h(BAA) = 3 = h^*(BAA)$ and $h(BAA) = h(BBB) + cost(o_2)$ 01 h_1 В А o_1, o_4 o_1, o_4 o_1, o_4 *o*₂ 03 h_2 В o_1, o_3 o_1, o_3 o_1, o_3 02 04 h_3 В А cost: 0

h is not admissible because $cost(o_2)$ is considered in h_2 and h_3

Is there anything we can do about this?

Solution 1:

We can ignore the cost of o_2 in h_2 or h_3 by setting its cost to 0. This is called a zero-one cost partitioning.

h is not admissible because $cost(o_2)$ is considered in h_2 and h_3

Is there anything we can do about this?

Solution 1:

We can ignore the cost of o_2 in h_2 or h_3 by setting its cost to 0. This is called a zero-one cost partitioning.

Solution 2: Consider a cost of $\frac{1}{2}$ for o_2 both in h_2 and h_3 .

Saturated Cost Partitionin

Summary 00

Combining Heuristics Admissibly: Example

h is not admissible because $cost(o_2)$ is considered in h_2 and h_3

Is there anything we can do about this?

Solution 1:

We can ignore the cost of o_2 in h_2 or h_3 by setting its cost to 0. This is called a zero-one cost partitioning.

Solution 2: Consider a cost of $\frac{1}{2}$ for o_2 both in h_2 and h_3 . This is called a uniform cost partitioning.

h is not admissible because $cost(o_2)$ is considered in h_2 and h_3

Is there anything we can do about this?

Solution 1:

We can ignore the cost of o_2 in h_2 or h_3 by setting its cost to 0. This is called a zero-one cost partitioning.

Solution 2: Consider a cost of $\frac{1}{2}$ for o_2 both in h_2 and h_3 . This is called a uniform cost partitioning.

General solution: satisfy cost partitioning constraint

$$\sum_{i=1}^n \mathit{cost}_i(o) \leq \mathit{cost}(o) ext{ for all } o \in O$$

h is not admissible because $cost(o_2)$ is considered in h_2 and h_3

Is there anything we can do about this?

Solution 1:

We can ignore the cost of o_2 in h_2 or h_3 by setting its cost to 0. This is called a zero-one cost partitioning.

Solution 2: Consider a cost of $\frac{1}{2}$ for o_2 both in h_2 and h_3 . This is called a uniform cost partitioning.

General solution: satisfy cost partitioning constraint

$$\sum_{i=1}^n \mathit{cost}_i(o) \leq \mathit{cost}(o)$$
 for all $o \in O$

What about o_1 , o_3 and o_4 ?

Summary 00

Cost Partitioning

Saturated Cost Partitioning

Content of this Course

Cost Partitioning

Definition (Cost Partitioning)

Let Π be a planning task with operators O.

A cost partitioning for Π is a tuple $\langle cost_1, \ldots, cost_n \rangle$, where

•
$$cost_i: O \to \mathbb{R}^+_0$$
 for $1 \le i \le n$ and

•
$$\sum_{i=1}^{n} cost_i(o) \le cost(o)$$
 for all $o \in O$.

The cost partitioning induces a tuple $\langle \Pi_1, \ldots, \Pi_n \rangle$ of planning tasks, where each Π_i is identical to Π except that the cost of each operator o is $cost_i(o)$.

Cost Partitioning: Admissibility (1)

Theorem (Sum of Solution Costs is Admissible)

Let Π be a planning task, $\langle cost_1, \ldots, cost_n \rangle$ be a cost partitioning and $\langle \Pi_1, \ldots, \Pi_n \rangle$ be the tuple of induced tasks.

Then the sum of the solution costs of the induced tasks is an admissible heuristic for Π , i.e., $\sum_{i=1}^{n} h_{\Pi_i}^* \leq h_{\Pi}^*$.

Cost Partitioning: Admissibility (2)

Proof of Theorem.

If there is no plan for state s of Π , both sides are ∞ . Otherwise, let $\pi = \langle o_1, \ldots, o_m \rangle$ be an optimal plan for s. Then

$$\sum_{i=1}^{n} h_{\Pi_{i}}^{*}(s) \leq \sum_{i=1}^{n} \sum_{j=1}^{m} cost_{i}(o_{j}) \qquad (\pi \text{ plan in each } \Pi_{i})$$
$$= \sum_{j=1}^{m} \sum_{i=1}^{n} cost_{i}(o_{j}) \qquad (comm./ass. of sum)$$
$$\leq \sum_{j=1}^{m} cost(o_{j}) \qquad (cost \text{ partitioning})$$
$$= h_{\Pi}^{*}(s) \qquad (\pi \text{ optimal plan in } \Pi)$$

Cost Partitioning Preserves Admissibility

In the rest of the chapter, we write h_{Π} to denote heuristic h evaluated on task Π .

Corollary (Sum of Admissible Estimates is Admissible)

Let Π be a planning task and let $\langle \Pi_1,\ldots,\Pi_n\rangle$ be induced by a cost partitioning.

For admissible heuristics h_1, \ldots, h_n , the sum $h(s) = \sum_{i=1}^n h_{i, \prod_i}(s)$ is an admissible estimate for s in \prod .

Cost Partitioning Preserves Consistency

Theorem (Cost Partitioning Preserves Consistency)

Let Π be a planning task and let $\langle \Pi_1, \ldots, \Pi_n \rangle$ be induced by a cost partitioning $\langle cost_1, \ldots, cost_n \rangle$.

If h_1, \ldots, h_n are consistent heuristics then $h = \sum_{i=1}^n h_{i, \prod_i}$ is a consistent heuristic for \prod .

Proof.

Let o be an operator that is applicable in state s.

$$egin{aligned} h(s) &= \sum_{i=1}^n h_{i,\Pi_i}(s) \leq \sum_{i=1}^n (cost_i(o) + h_{i,\Pi_i}(s\llbracket o
rbracket)) \ &= \sum_{i=1}^n cost_i(o) + \sum_{i=1}^n h_{i,\Pi_i}(s\llbracket o
rbracket) \leq cost(o) + h(s\llbracket o
rbracket) \end{aligned}$$

Introduction 0000000000 Saturated Cost Partitioning

Uniform Cost Partitioning

Content of this Course

- Principal idea: Distribute the cost of each operator equally (= uniformly) among all heuristics.
- But: Some heuristics do only account for the cost of certain operators and the cost of other operators does not affect the heuristic estimate. For example:
 - a disjunctive action landmark accounts for the contained operators,
 - a PDB heuristic accounts for all operators affecting the variables in the pattern.

Introduction Cost Partitioning Uniform Cost Partitioning Saturated Cost Partitioning Summar

- Principal idea: Distribute the cost of each operator equally (= uniformly) among all heuristics.
- But: Some heuristics do only account for the cost of certain operators and the cost of other operators does not affect the heuristic estimate. For example:
 - a disjunctive action landmark accounts for the contained operators,
 - a PDB heuristic accounts for all operators affecting the variables in the pattern.
- ⇒ Distribute the cost of each operator uniformly among all heuristics that account for this operator.

Example: Uniform Cost Partitioning for Landmarks

- For disjunctive action landmark *L* of state *s* in task Π' , let $h_{L,\Pi'}(s)$ be the cost of *L* in Π' .
- Then $h_{L,\Pi'}(s)$ is admissible (in Π').
- Consider set $\mathcal{L} = \{L_1, \dots, L_n\}$ of disjunctive action landmarks for state *s* of task Π .
- Use cost partitioning $\langle cost_{L_1}, \ldots, cost_{L_n} \rangle$, where

$$cost_{L_i}(o) = egin{cases} cost(o)/|\{L \in \mathcal{L} \mid o \in L\}| & ext{if } o \in L_i \ 0 & ext{otherwise} \end{cases}$$

- Let $\langle \Pi_{L_1}, \ldots, \Pi_{L_n} \rangle$ be the tuple of induced tasks.
- $h(s) = \sum_{i=1}^{n} h_{L_i, \prod_{L_i}}(s)$ is an admissible estimate for s in \prod .
- *h* is the uniform cost partitioning heuristic for landmarks.

Example: Uniform Cost Partitioning for Landmarks

Definition (Uniform Cost Partitioning Heuristic for Landmarks)

Let \mathcal{L} be a set of disjunctive action landmarks.

The uniform cost partitioning heuristic $h^{UCP}(\mathcal{L})$ is defined as

$$h^{\mathsf{UCP}}(\mathcal{L}) = \sum_{L \in \mathcal{L}} \min_{o \in L} c'(o)$$
 with

 $c'(o) = cost(o)/|\{L \in \mathcal{L} \mid o \in L\}|.$

Iniform Cost Partitioning

Saturated Cost Partitioning

Content of this Course

Idea

Heuristics do not always "need" all operator costs

- Pick a heuristic and use minimum costs preserving all estimates
- Continue with remaining cost until all heuristics were picked

Saturated cost partitioning (SCP) currently offers the best tradeoff between computation time and heuristic guidance in practice.

Cost Partitioning

niform Cost Partitioning

Saturated Cost Partitioning

Saturated Cost Function

Definition (Saturated Cost Function)

Let Π be a planning task and *h* be a heuristic. A cost function scf is saturated for *h* and *cost* if

• $scf(o) \le cost(o)$ for all operators o and

2
$$h_{\Pi_{scf}}(s) = h_{\Pi}(s)$$
 for all states s ,
where Π_{scf} is Π with cost function scf.

Minimal Saturated Cost Function

For abstractions, there exists a unique minimal saturated cost function (MSCF).

Definition (MSCF for Abstractions)

Let Π be a planning task and α be an abstraction heuristic. The minimal saturated cost function for α is

$$ext{mscf}(o) = ext{max}(\max_{\alpha(s) \stackrel{o}{\rightarrow} \alpha(t)} h^{\alpha}(s) - h^{\alpha}(t), 0)$$

Algorithm

Saturated Cost Partitioning: Seipp & Helmert (2014)

Iterate:

- Pick a heuristic h_i that hasn't been picked before.
 Terminate if none is left.
- 2 Compute h_i given current cost
- **③** Compute minimal saturated cost function $mscf_i$ for h_i
- Decrease cost(o) by $mscf_i(o)$ for all operators o

 $\langle \mathsf{mscf}_1, \ldots, \mathsf{mscf}_n \rangle$ is saturated cost partitioning (SCP) for $\langle h_1, \ldots, h_n \rangle$ (in pick order)
