Acyclic (Di-) Graphs

Acyclic

Similarly to connectedness, the presence or absence of cycles is an important practical property for (di-) graphs.

Definition (acyclic, forest, DAG)

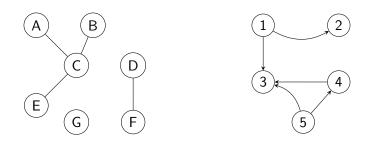

A graph or digraph G is called acyclic if there exists no cycle in G.

An acyclic graph is also called a forest.

An acyclic digraph is also called a DAG (directed acyclic graph).

German: azyklisch/kreisfrei, Wald, DAG

Acyclic (Di-) Graphs – Example

Trees

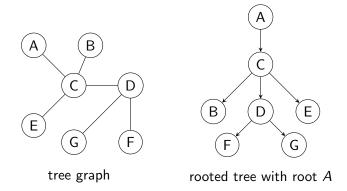

Definition (tree)

A connected forest is called a tree.

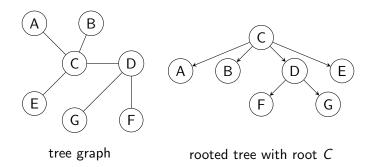

German: Baum

- Tree is also a word for a recursive data structure, which consists of either a leaf or a parent node with one or more children, which are themselves trees.
- This other kind of tree is also called a rooted tree to distinguish it from a tree as a graph.
- The two meanings of "tree" are distinct but closely related.

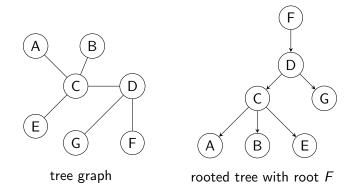

Tree Graphs vs. Rooted Trees – Example (1)

Tree Graphs vs. Rooted Trees – Example (2)

Tree Graphs vs. Rooted Trees – Example (3)

From Tree Graphs to Rooted Trees

General procedure for converting tree graphs into rooted trees:

- Select any vertex v. Make v the root of the tree.
- Initially, v is the only pending vertex, and there are no processed vertices.
- As long as there are pending vertices:
 - Select any pending vertex u.
 - Make all neighbours v of u that are not yet processed children of u and mark them as pending.
 - Change *u* from pending to processed.

We do not prove that this procedure always works. A proof of correctness can be given based on the results we show next.

Unique Paths in Trees

Unique Paths in Trees

Theorem

Let G = (V, E) be a graph.

Then G is a tree iff there exists exactly one path from any vertex $u \in V$ to any vertex $v \in V$.

Unique Paths In Trees – Proof (1)

Proof.

```
(⇒): G is a tree. Let u, v ∈ V.
```

We must show that there exists exactly one path from u to v.

We know that at least one path exists because G is connected.

It remains to show that there cannot be two paths from u to v.

If u = v, there is only one path (the empty one).

(Any longer path would have to repeat a vertex.)

We assume that there exist two different paths from u to v ($u \neq v$) and derive a contradiction.

Unique Paths In Trees – Proof (2)

Proof (continued).

Let $\pi = \langle v_0, v_1, \dots, v_n \rangle$ and $\pi' = \langle v_0', v_1', \dots, v_m' \rangle$ be the two paths (with $v_0 = v_0' = u$ and $v_n = v_m' = v$).

Let i be the smallest index with $v_i \neq v_i'$, which must exist because the two paths are different, and neither can be a prefix of the other (else v would be repeated in the longer path).

We have $i \ge 1$ because $v_0 = v'_0$.

Let $j \ge i$ be the smallest index such that $v_j = v'_k$ for some $k \ge i$.

Such an index must exist because $v_n = v'_m$.

Then $\langle v_{i-1}, \dots, v_{j-1}, v'_k, \dots, v'_{i-1} \rangle$ is a cycle,

which contradicts the requirement that G is a tree.

Unique Paths In Trees – Proof (3)

Proof (continued).

(\Leftarrow): For all $u, v \in V$, there exists exactly one path from u to v.

We must show that G is a tree, i.e., is connected and acyclic.

Because there exist paths from all u to all v, G is connected.

Proof by contradiction: assume that there exists a cycle in G,

 $\pi = \langle u, v_1, \dots, v_n, u \rangle$ with $n \geq 2$.

(Note that all cycles have length at least 3.)

From the definition of cycles, we have $v_1 \neq v_n$.

Then $\langle u, v_1 \rangle$ and $\langle u, v_n, \dots, v_1 \rangle$ are two different paths from u to v_1 , contradicting that there exists exactly one path from every vertex to every vertex. Hence G must be acyclic.

Leaves and Edge Counts in Trees and

Forests

Leaves in Trees

Definition

Let G = (V, E) be a tree.

A leaf of G is a vertex $v \in V$ with $deg(v) \leq 1$.

Note: The case deg(v) = 0 only occurs in single-vertex trees (|V| = 1). In trees with at least two vertices, vertices with degree 0 cannot exist because this would make the graph unconnected.

Theorem

Let G = (V, E) be a tree with $|V| \ge 2$.

Then G has at least two leaves.

Leaves in Trees - Proof

Proof.

Let $\pi = \langle v_0, \dots, v_n \rangle$ be path in G with maximal length among all paths in G.

Because $|V| \ge 2$, we have $n \ge 1$ (else G would not be connected).

We show that vertex v_n has degree 1: v_{n-1} is a neighbour in G.

Assume that it were not the only neighbour of v_n in G, so u is another neighbour of v_n . Then:

- If u is not on the path, then $\langle v_0, \ldots, v_n, u \rangle$ is a longer path: contradiction.
- If u is on the path, then $u = v_i$ for some $i \neq n$ and $i \neq n 1$. Then $\langle v_i, \ldots, v_n, v_i \rangle$ is a cycle: contradiction.

By reversing π we can show $\deg(v_0)=1$ in the same way.

Edges in Trees

Theorem

Let G = (V, E) be a tree with $V \neq \emptyset$.

Then |E| = |V| - 1.

Edges in Trees – Proof (1)

Proof.

Proof by induction over n = |V|.

Edges in Trees – Proof (1)

Proof.

Proof by induction over n = |V|.

Induction base (n = 1):

Then G has 1 vertex and 0 edges.

We get |E| = 0 = 1 - 1 = |V| - 1.

Edges in Trees - Proof (1)

Proof.

Proof by induction over n = |V|.

Induction base (n = 1):

Then G has 1 vertex and 0 edges.

We get
$$|E| = 0 = 1 - 1 = |V| - 1$$
.

Induction step $(n \rightarrow n+1)$:

Let G = (V, E) be a tree with n + 1 vertices $(n \ge 1)$.

From the previous result, G has a leaf u.

Let v be the only neighbour of u.

Let $e = \{u, v\}$ be the connecting edge.

Edges in Trees – Proof (2)

Proof (continued).

Consider the graph G' = (V', E') with $V' = V \setminus \{u\}$ and $E' = E \setminus \{e\}$.

- G' is acyclic: every cycle in G' would also be present in G (contradiction).
- G' is connected: for all vertices w ≠ u and w' ≠ u,
 G has a path π from w to w' because G is connected.
 Path π cannot include u because u has only one neighbour, so traversing u requires repeating v. Hence π is also a path in G'.

Hence G' is a tree with n vertices, and we can apply the induction hypothesis, which gives |E'| = |V'| - 1. It follows that

$$|E| = |E'| + 1 = (|V'| - 1) + 1 = (|V'| + 1) - 1 = |V| - 1.$$

Edges in Forests

Theorem

Let G = (V, E) be a forest.

Let C be the set of connected components of G.

Then |E| = |V| - |C|.

This result generalizes the previous one.

Edges in Forests - Proof

Proof.

Let $C = \{C_1, ..., C_k\}.$

For $1 \le i \le k$, let $G_i = (C_i, E_i)$ be G restricted to C_i , i.e., the graph whose vertices are C_i and whose edges are the edges $e \in E$ with $e \subseteq C_i$.

We have $|V| = \sum_{i=1}^{k} |C_i|$ because the connected components form a partition of V.

We have $|E| = \sum_{i=1}^k |E_i|$ because every edge belongs to exactly one connected component. (Note that there cannot be edges between different connected components.)

Every graph G_i is a tree with at least one vertex: it is connected because its vertices form a connected component, and it is acyclic because G is. This implies $|E_i| = |C_i| - 1$.

Putting this together, we get

$$|E| = \sum_{i=1}^{k} |E_i| = \sum_{i=1}^{k} (|C_i| - 1) = \sum_{i=1}^{k} |C_i| - k = |V| - |C|.$$

Characterizations of Trees

Characterizations of Trees

$\mathsf{Theorem}$

Let G = (V, E) be a graph with $V \neq \emptyset$.

The following statements are equivalent:

- G is a tree.
- ② G is acyclic and connected.
- **3** *G* is acyclic and |E| = |V| 1.
- G is connected and |E| = |V| 1.
- **5** For all $u, v \in V$ there exists exactly one path from u to v.

Characterizations of Trees – Proof (1)

Reminder:

- (1) G is a tree.
- (2) G is acyclic and connected.
- (3) G is acyclic and |E| = |V| 1.
- (4) G is connected and |E| = |V| 1.
- (5) For all $u, v \in V$ there exists exactly one path from u to v.

Proof.

We know already:

- (1) and (2) are equivalent by definition of trees.
- We have shown that (1) and (5) are equivalent.
- We have shown that (1) implies (3) and (4).

We complete the proof by showing $(3) \Rightarrow (2)$ and $(4) \Rightarrow (2)$

Characterizations of Trees – Proof (2)

Reminder:

- (2) G is acyclic and connected.
- (3) *G* is acyclic and |E| = |V| 1.

Proof (continued).

 $(3) \Rightarrow (2)$:

Because G is acyclic, it is a forest.

From the previous result, we have |E| = |V| - |C|, where C are the connected components of G.

Characterizations of Trees – Proof (2)

Reminder:

- (2) G is acyclic and connected.
- (3) *G* is acyclic and |E| = |V| 1.

Proof (continued).

 $(3) \Rightarrow (2)$:

Because G is acyclic, it is a forest.

From the previous result, we have |E| = |V| - |C|,

where C are the connected components of G.

But we also know |E| = |V| - 1. This implies |C| = 1.

Hence *G* is connected and therefore a tree.

Characterizations of Trees – Proof (3)

Reminder:

- (2) G is acyclic and connected.
- (4) G is connected and |E| = |V| 1.

Proof (continued).

$$(4) \Rightarrow (2)$$
:

In graphs that are not acyclic, we can remove an edge without changing the connected components: if $\langle v_0,\ldots,v_n,v_0\rangle$ $(n\geq 2)$ is a cycle, remove the edge $\{v_0,v_1\}$ from the graph. Every walk using this edge can substitute $\langle v_1,\ldots,v_n,v_0\rangle$ (or the reverse path) for it.

Characterizations of Trees – Proof (3)

Reminder:

- (2) G is acyclic and connected.
- (4) G is connected and |E| = |V| 1.

Proof (continued).

$$(4) \Rightarrow (2)$$
:

In graphs that are not acyclic, we can remove an edge without changing the connected components: if $\langle v_0, \ldots, v_n, v_0 \rangle$ $(n \ge 2)$ is a cycle, remove the edge $\{v_0, v_1\}$ from the graph.

Every walk using this edge can substitute $\langle v_1, \dots, v_n, v_0 \rangle$ (or the reverse path) for it.

Iteratively remove edges from G in this way while preserving connectedness until this is no longer possible. The resulting graph (V, E') is acyclic and connected and therefore a tree.

Characterizations of Trees – Proof (3)

Reminder:

- (2) G is acyclic and connected.
- (4) G is connected and |E| = |V| 1.

Proof (continued).

$$(4) \Rightarrow (2)$$
:

In graphs that are not acyclic, we can remove an edge without changing the connected components: if $\langle v_0, \ldots, v_n, v_0 \rangle$ $(n \ge 2)$ is a cycle, remove the edge $\{v_0, v_1\}$ from the graph.

Every walk using this edge can substitute $\langle v_1, \dots, v_n, v_0 \rangle$ (or the reverse path) for it.

Iteratively remove edges from G in this way while preserving connectedness until this is no longer possible. The resulting graph (V, E') is acyclic and connected and therefore a tree.

This implies |E'| = |V| - 1, but we also have |E| = |V| - 1. This yields |E| = |E'| and hence E' = E: the number of edges removable in this way must be 0. Hence G is already acyclic.
