Pattern Selection as Local Search

Pattern Selection as an Optimization Problem

Only one question remains to be answered now in order to apply PDBs to planning tasks in practice: How do we automatically find a good pattern collection?

The Idea

Pattern selection can be cast as an optimization problem:

► Given: a set of candidates (= pattern collections which fit into a given memory limit)

Planning and Optimization

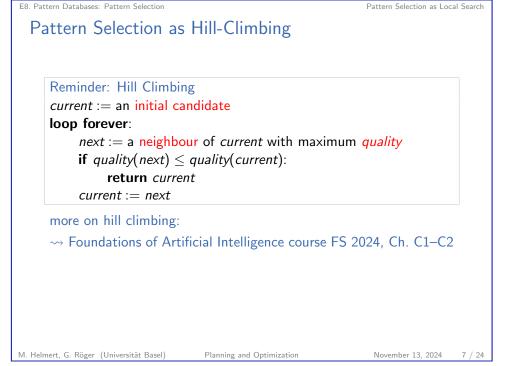

Find: a best possible candidate, or an approximation (= pattern collection with high heuristic quality)

M. Helmert, G. Röger (Universität Basel)

Pattern Selection as Local Search

November 13, 2024

5 / 24

How to solve this optimization problem? ▶ For problems of interesting size, we cannot hope to find (and prove optimal) a globally optimal pattern collection. Question: How many candidates are there? Instead, we try to find good solutions by local search. Two approaches from the literature: Edelkamp (2007): using an evolutionary algorithm ► Haslum et al. (2007): using hill-climbing \rightsquigarrow in the following: main ideas of the second approach

Pattern Selection as Hill-Climbing Reminder: Hill Climbing *current* := an initial candidate loop forever: *next* := a neighbour of *current* with maximum *quality* **if** quality(next) < quality(current): return current current := nextThree questions to answer to use this for pattern selection: **1** initial candidate: What is the initial pattern collection? **2** neighbourhood: Which pattern collections are considered next starting from a given collection? **9 quality**: How do we evaluate the quality of pattern collections?

E8. Pattern Databases: Pattern Selection

Initial Pattern Collection

1. Initial Candidate

The initial pattern collection is $\{\{v\} \mid v \text{ is a state variable mentioned in the goal formula}\}$.

Motivation:

patterns with one variable are the simplest possible ones and hence a natural starting point

Planning and Optimization

 non-goal patterns are trivial (~> Chapter E7), so would be useless

Search Neighbourhood: Basic Idea

The basic idea is that we

- start from small patterns with only a single variable,
- grow them by adding slightly larger patterns
- and prefer moving to pattern collections that improve the heuristic value of many states.

Search Neighbourhood

Which Pattern Collections to Consider Next

From this initial pattern collection, we incrementally grow larger pattern collections to obtain an improved heuristic.

2. Neighbourhood

The neighbours of \mathcal{C} are all pattern collections $\mathcal{C} \cup \{P'\}$ where

Planning and Optimization

- ▶ $P' = P \cup \{v\}$ for some $P \in C$,
- ► $P' \notin C$,
- ▶ all variables of P' are causally relevant for P',
- \triangleright P' is causally connected, and
- ► all pattern databases in C ∪ {P'} can be represented within some prespecified space limit.
- $\rightsquigarrow\,$ add one pattern with one additional variable at a time
- \rightsquigarrow use criteria for redundant patterns (\rightsquigarrow Chapter E7) to avoid neighbours that cannot improve the heuristic

Planning and Optimization

E8. Pattern Databases: Pattern Selection

Checking Causal Relevance and Connectivity

Remark: For causal relevance and connectivity, there is a sufficient and necessary criterion which is easy to check:

- \triangleright v is a predecessor of some $u \in P$ in the causal graph, or
- \triangleright v is a successor of some $u \in P$ in the causal graph and is mentioned in the goal formula.

Three approaches have been suggested:

Approaches for Evaluating Heuristic Quality

estimating the mean heuristic value of the resulting heuristic (Edelkamp, 2007)

Planning and Optimization

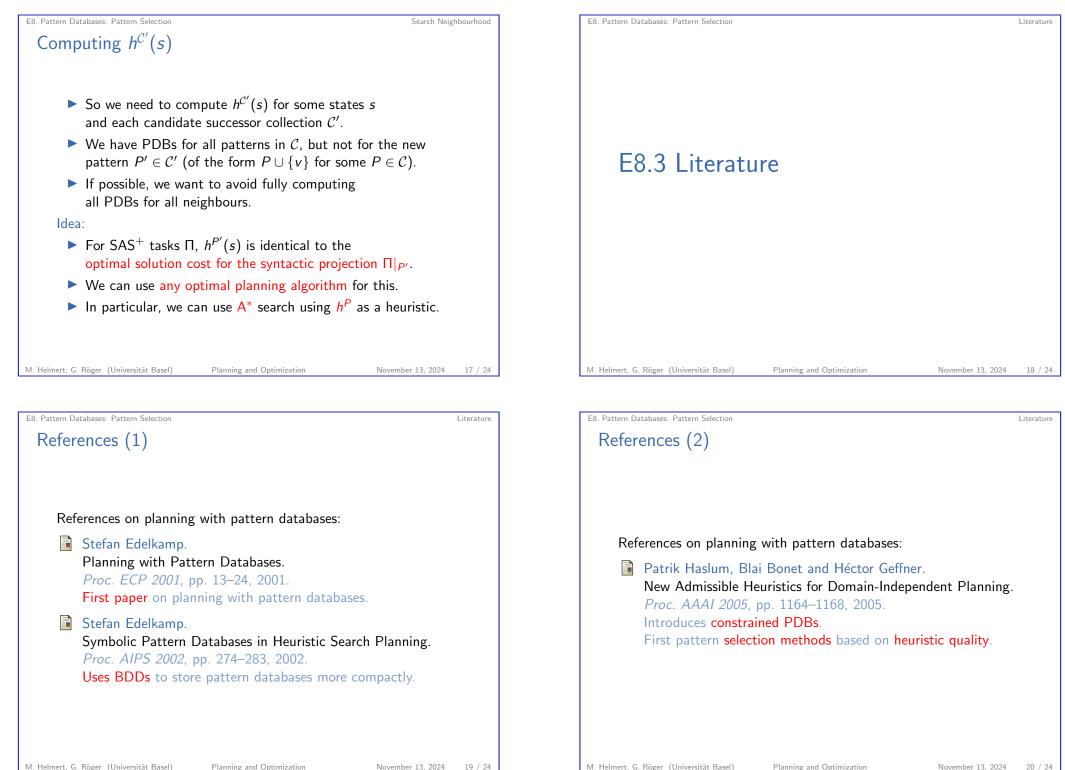

- estimating search effort under the resulting heuristic using a model for predicting search effort (Haslum et al., 2007; Franco et al., 2017)
- sampling states in the state space and counting how many of them have improved heuristic values compared to the current pattern collection (Haslum et al., 2007)

The last approach is most commonly used and has been shown to work well experimentally. E8. Pattern Databases: Pattern Selection

▶ This is perhaps the most critical point: without a good evaluation criterion, pattern collections are chosen blindly.

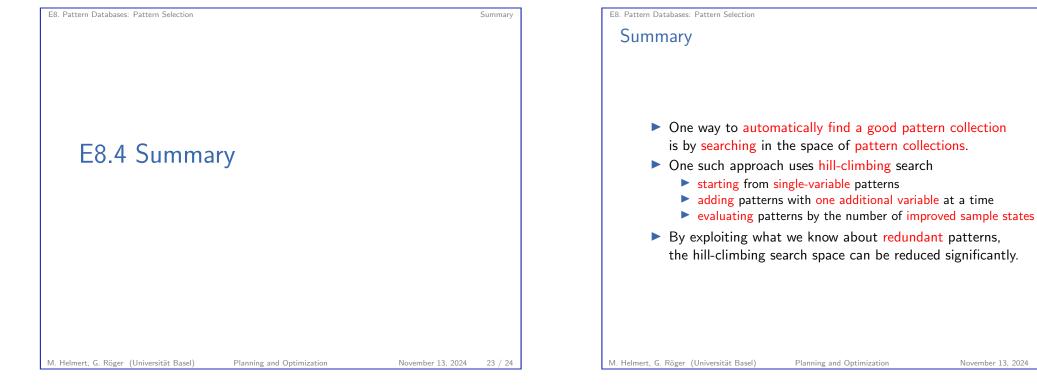

Evaluating the Quality of Pattern Collections

M. Helmert, G. Röger (Universität Basel) Planning and Optimization November 13, 2024 14 / 24 E8. Pattern Databases: Pattern Selection Search Neighbourhood Heuristic Quality by Improved Sample States 3. Quality • Generate *M* states s_1, \ldots, s_M through random walks in the state space from the initial state (according to certain parameters not discussed in detail). \blacktriangleright The degree of improvement of a pattern collection C'which is generated as a successor of collection Cis the number of sample states s_i for which $h^{\mathcal{C}'}(s_i) > h^{\mathcal{C}}(s_i)$. \blacktriangleright Use the degree of improvement as the quality measure for \mathcal{C}' .
