Content of the Course

Introduction

Introduction

Introduction

In the previous chapter, we used flow constraints to describe how often operators must be used in each plan.

Example (Flow Constraints)

Let Π be a planning problem with operators $\{o_{red}, o_{green}, o_{blue}\}$. The flow constraint for some atom a is the constraint

$$1 + Count_{Ogreen} = Count_{Ored}$$
 if

a is true in the initial state

ogreen produces a

a is false in the goal

Ored consumes a

In natural language, the flow constraint expresses that

Introduction

In the previous chapter, we used flow constraints to describe how often operators must be used in each plan.

Example (Flow Constraints)

Let Π be a planning problem with operators $\{o_{red}, o_{green}, o_{blue}\}$. The flow constraint for some atom a is the constraint

$$1 + Count_{Ogreen} = Count_{Ored}$$
 if

a is true in the initial state

ogreen produces a

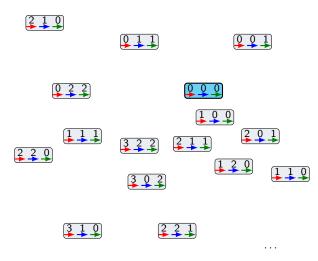

a is false in the goal

Ored consumes a

In natural language, the flow constraint expresses that every plan uses o_{red} once more than o_{green} .

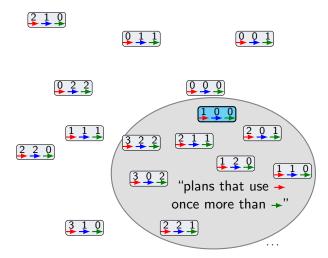

Introduction

Let us now observe how each flow constraint alters the operator count solution space.

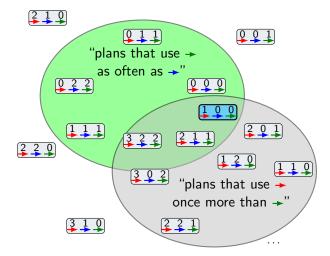

Introduction

Let us now observe how each flow constraint alters the operator count solution space.

Introduction

Let us now observe how each flow constraint alters the operator count solution space.

Operator-counting Framework

Operator Counting

Operator counting

- generalizes this idea to a framework that allows to admissibly combine different heuristics.
- uses linear constraints . . .
- ... that describe number of occurrences of an operator ...
- ... and must be satisfied by every plan.
- provides declarative way to describe knowledge about solutions.
- allows reasoning about solutions to derive heuristic estimates.

Operator-counting Constraint

Definition (Operator-counting Constraints)

Let Π be a planning task with operators O and let s be a state. Let V be the set of integer variables $Count_O$ for each $o \in O$.

A linear inequality over $\mathcal V$ is called an operator-counting constraint for s if for every plan π for s setting each Count $_o$ to the number of occurrences of o in π is a feasible variable assignment.

Operator-counting Heuristics

Definition (Operator-counting IP/LP Heuristic)

The operator-counting integer program IP_C for a set C of operator-counting constraints for state s is

Minimize
$$\sum_{o \in O} cost(o) \cdot Count_o$$
 subject to C and $Count_o \ge 0$ for all $o \in O$,

where O is the set of operators.

The IP heuristic h_C^{IP} is the objective value of IP_C, the LP heuristic h_C^{LP} is the objective value of its LP-relaxation. If the IP/LP is infeasible, the heuristic estimate is ∞ .

Operator-counting Constraints

- Adding more constraints can only remove feasible solutions.
- Fewer feasible solutions can only increase the objective value.
- Higher objective value means better informed heuristic
- ⇒ Have we already seen other operator-counting constraints?

Reminder: Minimum Hitting Set for Landmarks

Variables

Non-negative variable Applied for each operator o

Objective

Minimize $\sum_{o} cost(o) \cdot Applied_{o}$

Subject to

 \sum Applied_o ≥ 1 for all landmarks L $o \in L$

Operator Counting with Disjunctive Action Landmarks

Variables

Non-negative variable Count_o for each operator o

Objective

Minimize $\sum_{o} cost(o) \cdot Count_{o}$

Subject to

 $\sum_{o \in L} \mathsf{Count}_o \ge 1 \text{ for all landmarks } L$

Reminder: Post-hoc Optimization Heuristic

For set of abstractions $\{\alpha_1, \ldots, \alpha_n\}$:

Variables

Non-negative variables X_o for all operators $o \in O$ X_o is cost incurred by operator o

Objective

Minimize $\sum_{o \in O} X_o$

Subject to

$$\sum_{o \in O: o \text{ relev. for } \alpha} X_o \ge h^{\alpha}(s) \quad \text{for } \alpha \in \{\alpha_1, \dots, \alpha_n\}$$
$$X_o > 0 \qquad \text{for all } o \in O$$

Operator Counting with Post-hoc Optimization Constraints

For set of abstractions $\{\alpha_1, \ldots, \alpha_n\}$:

Variables

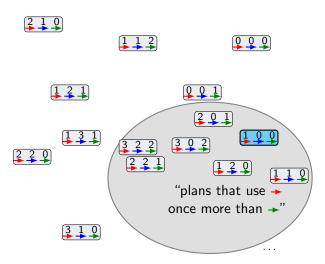

Non-negative variables $Count_o$ for all operators $o \in O$ $Count_o \cdot cost(o)$ is cost incurred by operator o

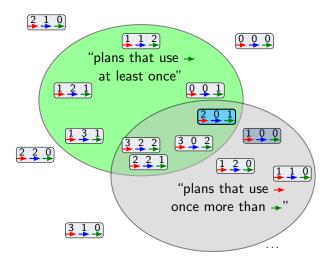

Objective

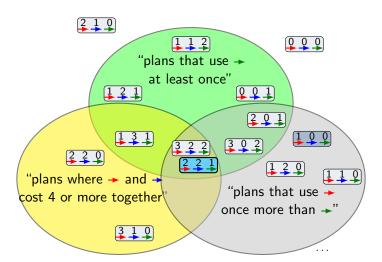

Minimize $\sum_{o \in O} cost(o) \cdot Count_o$

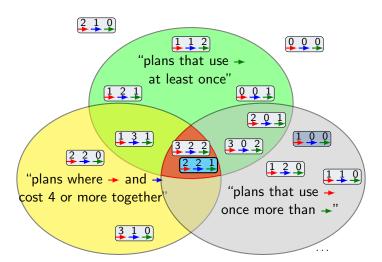

Subject to

$$\sum\nolimits_{o \in O: o \text{ relev. for } \alpha} cost(o) \cdot \mathsf{Count}_o \geq h^{\alpha}(s) \quad \text{for } \alpha \in \{\alpha_1, \dots, \alpha_n\}$$
$$cost(o) \cdot \mathsf{Count}_o \geq 0 \qquad \quad \text{for all } o \in O$$

Further Examples?

- The definition of operator-counting constraints can be extended to groups of constraints and auxiliary variables.
- With this extended definition we could also cover more heuristics, e.g., the perfect relaxation heuristic h^+

Properties

Admissibility

Theorem (Operator-counting Heuristics are Admissible)

The IP and the LP heuristic are admissible.

Proof.

Let C be a set of operator-counting constraints for state s and π be an optimal plan for s. The number of operator occurrences of π are a feasible solution for C. As the IP/LP minimizes the total plan cost, the objective value cannot exceed the cost of π and is therefore an admissible estimate.

Properties

Dominance

$\mathsf{Theorem}$

Let C and C' be sets of operator-counting constraints for s and let $C \subseteq C'$. Then $IP_C \le IP_{C'}$ and $LP_C \le LP_{C'}$.

Proof.

Every feasible solution of C' is also feasible for C. As the LP/IP is a minimization problem, the objective value subject to C can therefore not be larger than the one subject to C'.

Adding more constraints can only improve the heuristic estimate.

Heuristic Combination

Operator counting as heuristic combination

- Multiple operator-counting heuristics can be combined by computing h_C^{LP}/h_C^{IP} for the union of their constraints.
- This is an admissible combination.
 - Never worse than maximum of individual heuristics
 - Sometimes even better than their sum
- We already know a way of admissibly combining heuristics: cost partitioning.
 - ⇒ How are they related?

Connection to Cost Partitioning

Theorem

Let C_1, \ldots, C_n be sets of operator-counting constraints for s and $C = \bigcup_{i=1}^n C_i$. Then h_C^{LP} is the optimal general cost partitioning over the heuristics $h_{C_i}^{LP}$.

Proof Sketch.

In LP_C, add variables Countⁱ_o and constraints Count_o = Countⁱ_o for all operators o and $1 \le i \le n$. Then replace Count_o by Countⁱ_o in C_i .

Dualizing the resulting LP shows that $h_{\mathcal{C}}^{\mathsf{LP}}$ computes a cost partitioning. Dualizing the component heuristics of that cost partitioning shows that they are $h_{\mathcal{C}_i}^{\mathsf{LP}}$.

Comparison to Optimal Cost Partitioning

- some heuristics are more compact if expressed as operator counting
- some heuristics cannot be expressed as operator counting
- operator counting IP even better than optimal cost partitioning
- Cost partitioning maximizes, so heuristics must be encoded perfectly to guarantee admissibility. Operator counting minimizes, so missing information just makes the heuristic weaker.

Summary

Summary

- Many heuristics can be formulated in terms of operator-counting constraints.
- The operator counting heuristic framework allows to combine the constraints and to reason on the entire encoded declarative knowledge.
- The heuristic estimate for the combined constraints can be better than the one of the best ingredient heuristic but never worse.
- Operator counting is equivalent to optimal general cost partitioning over individual constraints.
