# How Good is Almost Perfect? 

Malte Helmert Gabriele Röger<br>Albert-Ludwigs-Universität Freiburg, Germany

AAAI 2008

## Outline

(1) Introduction
(2) Theoretical Results
(3) Experimental Results

4 Conclusion

## Optimal sequential planning

## Optimal sequential planning $=\mathrm{A}^{*}$ (or similar) <br> + admissible heuristic <br> (mostly)

## Folklore

## Everybody knows:

If a heuristic has constant absolute error, A* requires a linear number of node expansions.

## Comparison: Heuristic vs. breadth-first search

Actually, state-of-the art optimal sequential planners are not much better than breadth-first search.

Experiments of Helmert, Haslum \& Hoffmann (2007)

- BFHSP solved 37 tasks
- $\mathrm{A}^{*}+h^{\text {max }}$ solved 46 tasks
- $\mathrm{A}^{*}+h^{\mathrm{PDB}}$ solved 54 tasks
- blind search solved 42 tasks

## Are our heuristics bad?

Two possible explanations:

- Our heuristics aren't that good.
- There is something fishy going on.
(Or both.)

## Folklore + fine print

Everybody knows:
If a heuristic has constant absolute error, A* requires a linear number of node expansions.

## But. . .

This relies on several assumptions:

- fixed branching factor
- only a single goal state
- no transpositions

These assumptions do not hold in any common planning task!

## Almost perfect heuristics

Almost perfect heuristics differ from the perfect heuristic $h^{*}$ only by an additive constant:

## Definition

Define heuristic $h^{*}-c$ (for $c \in \mathbb{N}_{1}$ ) as

$$
\left(h^{*}-c\right)(s):=\max \left(h^{*}(s)-c, 0\right)
$$

$\rightarrow$ unlikely to be obtainable in practice

## The topic of this work

How many nodes must $\mathrm{A}^{*}$ expand for a planning task $\mathcal{T}$, given an almost perfect heuristic $h^{*}-c$ ?

## Definition

$$
\begin{aligned}
N^{c}(\mathcal{T}):= & \text { number of states } s \\
& \text { with } g(s)+\left(h^{*}-c\right)(s)<h^{*}(\mathcal{T})
\end{aligned}
$$

$\rightsquigarrow$ If this number grows fast with scaling task size, we have a problem.

## Objective

Results for $N^{c}(\mathcal{T})$ for IPC domains
$\rightarrow$ Focus on domains in APX

## Outline

(1) Introduction
(2) Theoretical Results
(3) Experimental Results
4. Conclusion

## Our goal

Find sequence $\left(\mathcal{T}_{n}\right)$ of scaling tasks for which $N^{c}\left(\mathcal{T}_{n}\right)$ grows exponentially, even for small values of $c$.

## GRIPPER

- $\mathcal{T}_{n}$ : Task with $n$ balls
- $S_{n}$ : Total number of reachable states of $\mathcal{T}_{n}$

$$
S_{n}=2 \cdot\left(2^{n}+2 n 2^{n-1}+n(n-1) 2^{n-2}\right)
$$

## GRIPPER

## Theorem

## Theorem

Let $n \in \mathbb{N}_{0}$ with $n \geq 3$.
If $n$ is even, then

- $N^{1}\left(\mathcal{T}_{n}\right)=N^{2}\left(\mathcal{T}_{n}\right)=\frac{1}{2} S_{n}-3$
- $N^{c}\left(\mathcal{T}_{n}\right)=S_{n}-2 n-2$ for all $c \geq 3$.

If $n$ is odd, then

- $N^{1}\left(\mathcal{T}_{n}\right)=N^{2}\left(\mathcal{T}_{n}\right)=S_{n}-3$
- $N^{c}\left(\mathcal{T}_{n}\right)=S_{n}-2$ for all $c \geq 3$.

## GRIPPER <br> Proof

## Proof sketch

- $n$ is even
- states with an even number of balls in each room
- basically all are part of an optimal plan
- states with an odd number of balls in each room
- all are part of plans of length $h^{*}\left(\mathcal{T}_{n}\right)+2$
- $n$ is odd
- basically all states are part of an optimal plan

## Miconic-Simple-AdL

initial state

goal state

- $\mathcal{T}_{n}$ : Task with $n$ passengers (and $n+1$ floors)
- $S_{n}$ : Total number of reachable states of $\mathcal{T}_{n}$

$$
S_{n}=3^{n}(n+1)
$$

## Miconic-Simple-AdL

## Theorem

For all $c \geq 4$ :

$$
N^{c}\left(\mathcal{T}_{n}\right)=S_{n}-\left(2^{n}-1\right)(n+1) .
$$

## BLocksworld

$\mathcal{T}_{n}$ : Task with $n$ blocks $(n \geq 2)$

## Blocksworld

## Theorem

## Theorem

$$
N^{1}\left(\mathcal{T}_{n}\right)=4 \cdot \sum_{k=0}^{n-3} B_{k}+3 B_{n-2}+1
$$

| $n$ | $N^{1}\left(\mathcal{T}_{n}\right)$ | $n$ | $N^{1}\left(\mathcal{T}_{n}\right)$ |

## Outline

(1) Introduction
(2) Theoretical Results
(3) Experimental Results
4. Conclusion

## Question

## Theoretical results

There exist task families for which the number of states expanded by $h^{*}-c$ grows exponentially, even for small $c$.

## Interesting question

Can we observe this behaviour in practice?
$\rightarrow$ Experiments with IPC tasks

## Problem

- Values $N^{c}(\mathcal{T})$ are defined in terms of $h^{*}$.
- Usually $h^{*}$ cannot be determined efficiently.

Naive way of computing $N^{c}(\mathcal{T})$

- Completely explore the state space of $\mathcal{T}$.
- Search backwards from the goals to determine the $h^{*}(s)$ values.
$\rightarrow$ Observation: Generating all states is not necessary.

## Search space

$\rightsquigarrow$ Poster session: today, 6:00-9:30 PM

## Results

(1) Introduction
(2) Theoretical Results
(3) Experimental Results

4 Conclusion

## Dismal prospects

Depressing theoretical and experimental results

- Other (similar) search techniques cannot perform better than $\mathrm{A}^{*}$.
- With other (real) heuristics it gets worse.

## What is the cause of this behaviour?

## Main problem

- many independently solvable subproblems which can be arbitrarily permuted
- many possible orders

Why is this not common knowledge?
$\rightarrow$ does not happen in 15-Puzzle, Rubik's Cube, etc.

## What do the results mean for us?

Some possible conclusions:

## Conclusion? <br> We need heuristics that are better than almost perfect. <br> How feasible is this?

## Conclusion?

We need more search enhancements.
Look to domain-dependent search for guidance?

## What can the search community offer us?

Domain-specific search enhancements for Sokoban (Junghanns and Schaeffer, 2001):

- transposition table
- move ordering
- deadlock tables
- tunnel macros
- goal macros
- goal cuts
- pattern search
- relevance cuts
- overestimation
- rapid random restart

$\rightsquigarrow$ irrelevant to analysis
$\rightsquigarrow$ Poster session: today, 6:00-9:30 PM

## General search enhancements

Some techniques that might work in general:

- partial-order reduction
- symmetry elimination
- problem simplification

## What do the results mean for us?

Some alternative conclusions:

## Conclusion?

Heuristic search doesn't cut it.
What about more global reasoning methods, such as
SAT planning, or symbolic exploration techniques like breadth-first search with BDDs?

## Conclusion?

Optimal planning, beyond a certain point, is too hard.
We can hope to scale a bit better than blind search, but not very far. Maybe study near-optimal planning in a more principled way instead?

## The end

## Thank you for your attention!
